The Western Electrician.

EVERY SATURDAY.

MASS. INSTITUTE OF TECHNOLOGY NOV 17 1894 LIBRARY.

621.305

MASSACHUSETTS INSTITUTE OF TECHNOLOGY DEPARTMENT OF PHYSICS

VOLUME IX.

NUMBERS 1--26.

July 4–December 26, 1891.

ELECTRICIAN PUBLISHING COMPANY,
CHICAGO.

INDEX.

Accounts, Uniformity in the Method of Keeping Central Station. By J. J. Burleigh. And Discussion (National Electric Light Association)....170, 171
Accumulators in Belgium.... 75
Accumulators, Patent Litigation Over....66, 67
Actinism a Species of Electrolysis, Is? By Edwin J. Houston (Franklin Institute)....334, 335
Adams' Dynamo and Motor. Illustrated.... 186
Advantages of the Electric Street Railway, by H. B. Prindle....79, 80
African Explorer, The Electric Light in the Service of the. Illustrated.... 8
Aging Liquors by Electricity. Illustrated.... 344
Air Gap and the Shape of the Poles to the Performance of Dynamo Electric Machinery, On the Relation of the. By Harris J. Ryan. And Discussion (American Institute of Electrical Engineers). Illustrated....206, 207, 208, 220, 221
Allen Flats, Chicago, Lighting Plant at the. Illustrated.... 47
Alternating Currents, Distribution and Care of, Discussion of T. Carpenter Smith's Paper Read Before the Providence Convention (National Electric Light Association)....164, 165
Alternate Current Motor, Brown's Three Phase. Illustrated.... 274
Alternating Current Motor, The Hubin-Le Blanc. Illustrated.... 46
Alternate Currents of Very High Frequency and Their Application to Methods of Artificial Illumination, Experiments with. By Nikola Tesla. Illustrated. (American Institute of Electrical Engineers)....18, 19, 21, 22, 23, 24
Alternating Current Telephone Transmitter, O'Connell's. Illustrated.... 300
Alternating Dynamos, New. Illustrated.... 275
Alternating Electric Systems and Their Physical Hazards. By George P. Low....335, 336
Alternator, National Self Contained. Illustrated.... 193
Alternating Plant, English. Illustrated.... 186
Alternating Systems, A Central Station Combining the Advantages of both Continuous and. By H. Ward Leonard. And Discussion (National Electric Light Association)....168, 169 170
Alternating System in Long Distance Transmission, The. By F. B. Badt (Communication).... 117
Aluminum, Production of....24, 25
Amalgamating Process, Electrical Illustrated.... 319
Amateur Electricians.... 117
America, Following the Lead of.... 330
American Institute of Electrical Engineers..17, 18, 19, 21, 22, 23, 24, 201, 206, 207, 208, 219, 220, 221, 272, 277, 278, 279, 280, 303, 305, 306, 377, 378, 379
American International Telephone Cable.... 117
American Street Railway Association....87, 196, 205, 243
American Street Railway Association, Proceedings of the Annual Convention at Pittsburg.
President's Address.... 256
Report of the Executive Committee....256, 257
Treasurer's Report.... 257
Perfect Electric Motor. By H. A. Everett, and Discussion....257, 258, 259
The Dependent—Overhead or Underground—System of Electric Motive Power. By George W. Mansfield, and Discussion..259, 261, 262, 263
The Independent—Storage or Primary Battery—System of Electric Traction. By Knight Neftel. And Discussion....263, 264
Resolutions....264, 266
Standards in Electric Railway Practice. By O. T. Crosby, and Discussion....264, 265, 266
Election of Officers.... 266
The New President.... 266
Delegates in Attendance....266, 267
Applications for Membership.... 267
The Banquet.... 267
Excursions and Entertainments.... 267
The Souvenir Badges. Illustrated.... 268
Convention Notes, Exhibits and Personals.... 268
Apparatus for Indicating Variations of Pressure in Gaseous Currents. Illustrated.... 75
Arc Lamp Hanger. Illustrated.... 106
Arc Lighting and Hazards. by Geo. P. Low....93, 94
Arc Lighting System as Practiced in the "Municipal" of St. Louis, Some Details of the Care and Management of an. By J. I. Ayer, and Discussion (National Electric Light Association)....179, 180, 181
Armstrong's Starting Device for Motors at a Distance. Illustrated.... 372, 373
Asbestos Manufacturers Consolidate, Prominent.... 65
Augusta Exposition, Electricity at the.... 320
Automatic Detector of Fire Damp in Coal Mines. Illustrated.... 194
Automatic Pay Call Box for Telephones. Illustrated. 102
Avoiding Dead Centers, Micheles' Ingenious Device for. Illustrated.... 120

Bain's Compensating Voltmeter. Illustrated.... 249
Ball Engine, Cross Compound. Illustrated.... 133
Battery Cells, Samples. Illustrated.... 33
Battry Chemistry of the Primary. By Frank K. Irving....361, 362
Batteries, Grouping. By Frank K. Irving.... 320
Battery, Midget. Illustrated.... 350
Battery, The Champion. Illustrated.... 292
Battery, The Gladiator Dry. Illustrated.... 220
Battery with an Iron Electrode Secondary. Illustrated.... 356
Beckley, John N., with portrait.... 85
Bell Telephone Stock.... 64
Bell, The Door Knob Alarm. Illustrated.... 302
Berliner Patent. Illustrated....315, 316
Block Signal Problem, Solution of the, by H. Ward Leonard. Illustrated....221, 222

Bloomington, Ill., Electric Road at..... 47
Board of Trade and the Telegraph..... 183
Book Table, the.....50, 75, 116
Boston Street Railway Officials in Chicago..... 219
Bridges Operated by Electric Power. Illustrated..85, 86
British Postmaster General, Death of the..... 133
Bradbury-Stone Storage Battery Car at Sioux City, Ia. Illustrated..... 272
Brush Generator and Motor. Illustrated..... 193
Buffalo Street Railway Company Electric System of. Illustrated..... 103
Burning of Wiman's Electric Light Plant at St. George, Staten Island. Illustrated..... 87
Business, (Notes).....14, 28, 42, 56, 70, 84, 98, 112, 126, 142, 156, 184, 198, 212, 226, 240, 254, 270, 283, 284, 297, 298, 312, 325, 326, 340, 354, 368, 382
Byllesby, Henry M., with portrait..... 57

C. and C. Fan Motor. New. Illustrated..... 35
Cable Road Dismantled, the Oldest..... 199
Camp's Conduit. Illustrated..... 303
Canadian Electrical Association, Proposed..291, 292, 347
Canada's International Exhibition..... 29
Carbons Used in Arc Lighting, Different Forms of, by E. P. Warner, (National Electric Light Association)..... 181
Carriage, an Electric. Illustrated..... 333
Cassel, Germany, Electric Plant at. Illustrated.244, 245
Census, Electrical Industries and the.....208, 251
Census, Electrical Statistics for the (National Electric Light Association).....174, 175
Central Stations Operated by Water Power. By George A. Redman. Discussion (National Electric Light Association).....165, 167, 168
Centrifugal Machines, Application of Electricity to. Illustrated..... 319
Chemistry of the Primary Battery. By Frank K. Irving.....361, 362
Chicago Amateur Electric Society..... 196
Chicago and Milwaukee, Proposed Electric Road Between.....30, 50
Chicago Arc Light & Power Company's Station Burned..... 333
Chicago City Lighting Plant..... 46
Chicago Edison Company.....49, 117
Chicago Edison Company's Operations..... 92
Chicago Electric Club.....74, 87, 245, 268, 269, 270, 306, 319, 333 342, 348, 349, 350, 361, 362, 380
Chicago Electric Club and the Electrical Congress of 1893..... 234
Chicago Electric Road, Proposed New.....7, 88, 89, 183, 184, 347
Chicago Herald Building's New Electrical Equipment. Illustrated..... 329
Chicago News Electrical Plant. Illustrated.....375, 376
Chicago's Parks and Boulevards, Lighting..... 355
Chicago Society of Operative Electricians..... 301
Chicago Telephone Exchange, the New Ticket Distributor at the..... 57
Chicago Trolley Clamp. Illustrated..... 65
Chicago West Side "L" Road Syndicate, Thomson-Houston Company and the..... 29
Chicago's West Side Suburbs, an Electric Road for.. 43
Chicago, Cable Roads in..... 370
Chicago, Municipal Lighting in..... 373
Chilian War Affecting Telephone Interests..... 65
China Switch, New Electrix. Illustrated..... 334
Cigar Lighter, Electric. Illustrated..... 328
Cincinnati, O., (Correspondence).....124, 210, 237, 309
Circuit Protector, The W. B. G. Illustrated..... 24
City & South London Railway..... 92
City & South London Electric Railway, Advantages of the..... 281
Cleveland, O., (Correspondence).....154, 224, 238, 338
Clock, Electric. Illustrated..... 10
Coal Cutter, Solenoid. Illustrated..... 133
Collier's Audible Telephone. Illustrated..... 33
Columbia College, Electrical Engineering at..... 364
Columbia System, The. Illustrated..... 217
Columbus, O., (Correspondence)..... 238
Combination Electric Railway Section Insulator and Lightning Arrester. Illustrated..... 330
Composing Room, Electricity in the..... 301
Construction and Operation of Cable and Electric Railways.....37, 38
Constitution, Report of Committtee on (National Electric Light Association)..... 162
Continuous and Alternating Systems, A Central Station Combining the Advantages of both the, By H. Ward Leonard. And Discussion. (National Electric Light Association) 168, 169, 170
Continuous Current Motor by Alternating Current, Driving a. Illustrated..... 49
Contract, A 2,700 Light..... 272
Concord, N. H. (Correspondence).....55, 210
Condenser, Tesla's Oil Insulated. Illustrated..... 365
Cone, Evans' Friction. Illustrated..... 280
Congress of Electricians, International. By Henry S. Carhart..... 233
Controversy Over a Franchise..... 16
Cope Automatic Wire Puller. Illustrated..... 150
Copper Men Think, What the 91
Copper Production in the United States.....65, 66
Cornell Men at Chicago..... 331
Corn Palace, Electricity at the. Illustrated..... 331
Correspondence.....11, 12, 13, 25, 26, 38, 39, 40, 53, 54, 55, 67, 68, 69, 81, 82, 94, 95, 96, 109, 110, 111, 123, 124, 140, 153, 154, 196, 209, 210, 224, 237, 238, 252, 253, 270, 281, 282, 294 295, 296, 308, 309, 310, 322, 323 336 337, 338 351 352, 364, 365, 366, 380, 381
Cranes, Electric and Steam..... 314
Crane, English Traveling. Illustrated..... 331
Cuadros' Apparatus for Automatically Regulating the Firing of Ordnance on Ships. Illustrated.... 35
Currents from the Sun, Electric..... 219
Cut out, Wheeler's. Illustrated 330
Crystal Palace, Electrical Exhibition.....50, 130

Darmstadt, Central Stations at Mulhausen and. Illustrated.....313, 314
Data, Report of Committee on. By A. J. DeCamp. (National Electric Light Association)..... 163
Dental Drill, Electrically Operated. Illustrated..... 220
Dentistry, Electricity as a Motive Power in. By Peter Brown, L. D. S..... 237
Denver, Colo. (Correspondence) 96, 153, 154, 323, 337, 338
Dependent-Overhead or Underground—System Electric Motive Power, The. By Geo. W. Mansfield. And Discussion. (American Street Railway Association).....259, 261, 262, 263
Detroit, Electrical Decorations at..... 143
Detroit, Mich. (Correspondence).....12, 13, 40
Detroit, New Railway Management for..... 64
Detroit, Rapid Transit for..... 7
Diminutive Electric Light Plant. Illustrated..... 117
Distribution and Care of Alternating Currents, Discussion of T. Carpenter Smith's Paper, Read Before the Providence Convention. (National Electric Light Association).....164, 165
Double Carbon Suit, New.....319, 327
Drilling Machine, The Edco Electrical. Illustrated.. 371
Drills at Lost Chance Mine, Idaho, Electric Percussion. Illustrated..... 33
Driving a Continuous Current Motor by Alternating Current. Illustrated..... 49
Druggist's Danger Signal. Illustrated..... 302
Dubuque Storage Battery Road..... 308
Dynamos at the Frankfort Exposition, Largest. Illustrated..... 149
Dynamos at the Frankfort Exhibition, One of the. Illustrated..... 370
Dynamo, La Roche Alternating. Illustrated..... 202
Dynamo, La Roche Arc. Illustrated..... 280
Dynamo, La Roche Special. Illustrated 359
Dynamo Men, Useful Hints for. Illustrated. 302
Dynamos, New Alternating. Illustrated..... 275
Dynamo, New C. & C. Illustrated.....274, 275
Dynamo, Parsons' Steam Turbine. Illustrated..... 102
Dynamo, Perret, on the Romola. Illustrated..... 9
Dynamo, Prentice. Illustrated..... 9
Dynamos, Riker Low Speed Motors and. Illustrated. 376

Easton Electric Company's Apparatus. Illustrated.. 291
Edco Electrical Drilling Machine, The. Illustrated.. 371
Edison Convention in New York.....79, 89, 106, 107
Edison Electric Illuminating Company at Paterson, N. J., Stations of the 59, 60, 61
Edison Electric Locomotive for Mines and Mills. Illustrated..... 9
Edison's Inventions, Claims an Interest in..... 65
Edison Men in Council..... 347
Edison Pressure Indicator. Illustrated..... 202
Edison Removal in Chicago..... 116
Editorial.....6, 20, 34, 48, 62, 76, 90, 104, 118, 134, 148, 166, 190, 204, 218, 232, 246, 260, 276, 290, 304, 318, 332, 346, 360, 374
Electric Clock. Illustrated..... 10
Electric Cranes..... 153
Electric Heating..... 92
Electric Light in the Service of the African Explorer, The. Illustrated..... 8
Electric Light, New Use for..... 71
Electric Light Plant for the Masonic Temple, Chicago 57
Electric Light Plant in the Land of the Midnight Sun. Illustrated..... 32
Electric Light Plant in the New York *World* Building. Illustrated..... 89
Electric Light Plant on the Virginia. Illustrated 114, 115
Electric Light Plants Operated by Gas Companies, Growth of..... 33
Electric Lighting, Data on (National Electric Light Association)..... 164
Electric Lighting (Notes).....13, 27, 41, 55, 69, 83, 96, 97, 111, 125, 141, 154, 184, 197, 211. 225, 238 239, 253, 282, 283, 296, 324, 338, 353, 367, 381
Electric Mining (Notes). 13, 27, 55, 56, 70, 83, 79, 111, 125, 141, 155, 184, 211, 225, 239, 325, 338, 367, 381
Electric Motive Power for Street Railways. Report of the Committee on. By John N. Beckley. A Discussion. (New York State Street Railway Association).....188, 189, 191, 192
Electric Motor (Notes)..... 69, 83, 111, 211, 325
Electric Motors for Switching and Suburban Work on Steam Railroads.....74, 75
Electric Organs, by James Swinburne.....10, 11
Electric Percussion Drills at Lost Chance Mine, Idaho. Illustrated..... 33
Electrical Plant, *Chicago News*. Illustrated 375, 376
Electric Power Transmission. By F. B. Badt. 60, 61, 121
Electric Power Transmission Plant at Aspen, Colo. Illustrated.....1, 2
Electric Railway, (Notes).....13, 27, 41, 55, 69, 83, 97, 111, 125, 141, 154, 155, 184, 197, 211, 225, 239 253, 283, 297, 324, 325, 338, 353, 367, 381
Electric Railway, Evanston..... 49
Electric Railway Construction and Operation and the Consideration of Their Connection with Central Station Interests. By C. J. Field. A Discussion. (National Electric Light Association) .. 177, 178, 179
Electric Railway. Future of the. By Frank J. Sprague.....139, 140
Electric Railway Patents, George F. Green's. Illustrated..... 375
Electric Railway System, New..... 38
Electric Railways, Three Years' Development of. By Eugene Griffin. And Discussion. (National Electric Light Association.).....171, 172, 173, 174
Electric Road at Bloomington, Ill..... 47
Electric Road Between Chicago and Milwaukee, Proposed.....30, 50
Electric Road for Chicago's West Side Suburbs, An.. 43
Electric Road from Jersey City to Newark, Proposed. 36
Electric Street Railway, Advantages of the. By H. B. Prindle.....79, 80
Electric Wires in Rochester, N. Y..... 7
Electrical Advancement in England, A London Electrician's Opinion on..... 91
Electrical Census of the State of New York..... 79
Electrical Congress, Carl Hering and the. (Communication)..... 364
Electrical Development in the Northwest..... 30
Electrical Engineering as a Profession in England. 306, 307
Electrical Executions, The..... 36
Electrical Grave Annunciator, An Illustrated..... 35
Electrical Method of Shaping Metal Bars. Illustrated..... 116
Electrical Patents. (Issued in the United States)... 14, 28, 42, 56, 70, 84 98, 112, 126, 142, 156, 198, 212, 226, 240, 254, 284, 298, 312, 326, 340, 354, 368, 382
Electrical Signaling on Board the Chicago in New York Harbor. Illustrated.....72, 73, 74
Electrical Sky Effects.....149, 150
Electrically Driven Ship's Winch. Illustrated..... 91
Electrically Regulated Clocks in Chicago..... 248
Electricity at "A Night in Pekin"..... 57
Electricity for Submarine Torpedoes. Illustrated... 77
Electricity in a Chicago Rolling Mill. Illustrated... .....43, 44, 45
Electricity in Life. By Edward P. Jackson..... 153
Electricity on our Great Railways. By H. S. Wynkoop. 114, 115, 116
Electric Magnet in Eye Surgery, The. By Silvanus P. Thompson and J. Tatham Thompson. Illustrated..... 37
Electric Therapeutical Office Outfit. Illustrated ... 150
Elevator at the Chicago Athenæum, Electric. Illustrated..... 248
Elevator, Transmitting Power From an Electric Motor to a Hand. Illustrated..... 361
Elliott Pull-off. Illustrated..... 362
Engine for Central Station Plants, New. Illustrated 216
Engine, Weston Automatic. Illustrated..... 219
Engine, Weston Compound. Illustrated..... 281
English Electrical Exhibition.....119, 120
Enterprise in forwarding War News..... 133
Enterprising Suprintendent, An..... 107
Eternal City, Electric Lights for..... 293
Evans Friction Cone. Illustrated..... 280
Evanston's Electric Railway..... 49
Exaggerations, Electrical..... 320
Exhibits at the Pittsburg Convention, Street Railway. Illustrated.....255, 256, 257, 258, 259, 261
Experiment on the Zipernowski Electric Railway With a Vertical Track. Illustrated.....16, 17
Experiments With Alternate Currents of Very High Frequency and Their Application to Metoods of Artificial Illumination. By Nikola Tesla. Illustrated. (Am Inst. of El. Eng.)..18, 19, 21, 22, 23 24

Fair Building, Chicago, The Lighting Plant in the. Illustrated 369, 370
Fan Motor, New C. & C. Illustrated..... 35
Fan Outfit, La Boiteaux. Illustrated..... 24
Faraday's Religious Life..... 36
Ferranti, How About..... 133
Ferranti System, The..... 59
Feed Water Heater, Improved. Illustrated..... 78
Feeding Mechanism for Arc Lamps, New. Illustrated..... 119
Fire Apparatus, Portable Electric. Illustrated..... 242
Fire Department Chief's Buggy, Electric Light on a. Illustrated..... 345
Firemen Aided by Electricity..... 49
Firemen's Convention, Electricity at the..... 107
Fires in Chicago, Two Central Station. Illustrated. 343
Fiske Range Finder..... 356
Flying by Means of Electricity..... 94
Forging Steel by Electricity..... 89
Frankfort Electrical Congress..... 234
Frankfort Electrical Exhibition..... 91
Frankfort Electrical Exhibition. By F. B. H. Paine. 109
Frankfort Electrical Exhibition. Illustrated..... 213
Frankfort Exhibition, A Glimpse of the Siemens & Halske Exhibit at the. Illustrated.....228, 229
Frankfort Exhibition and the World's Fair. Illustrated.....285, 286, 287, 288
Frankfort Exhibition, Electric Boat at the. Illustrated..... 228
Frankfort Exhibition, Electric Race Track at the. Illustrated..... 241
Frankfort Exhibition, One of the Dynamos at the. Illustrated..... 370
Frankfort Exhibition, Schuckert Dynamo at the Illustrated..... 242
Frankfort, Germany, Transformer, House of the High Tension Transmission System. Illustrated..... 301
Frankfort-Offenbach Electric Railroad. Illustrated.....341, 342
Frankfort, The Iron Tower at. Illustrated..... 231
Frankfort Transmission, The Lauffen. Illustrated.230, 231
Franklin Experimental Club..... 220, 373
Franklin Institute, Electrical Section of.....334, 335
Frey's Compensating Shunts for Galvanometers. Illustrated.....376, 377
Frisbie Electric Elevator. Illustrated..... 165

Galvanometer Battery Gauge, Pocket. Illustrated.. 234
Gas Interests, Electricity Beneficial to the..... 38
Gearless Motors for Street Railways. Illustrated..88, 89
Generators, Polyphasal, by M. I. Pupin, Ph. D. Illustrated. (American Institute Electrical Engineers).....377, 378, 379

Goubert's Watt Meter. Illustrated 77
Governor for Steam Engines, Improved. Illustrated. 78
Grant Locomotive Works, Electricity at the 234
Grassot Electric Meter. Illustrated 119
Grave Annunciator, An Electrical. Illustrated 35
Green's Electric Railway Patents, George F. Illustrated 375
Gregory's Electrically Driven Model of an Ocean Steamer. Illustrated 107

Hale's Wire Cutter for Firemen. Illustrated 362
Halm, W. G., Death of 343
Harrisburg, Trouble at 146
Harvey Electric Road, Proposed 45
Havana Electric Light Station 307
Heat in its Relation to Electricity and its Influence Upon the Animal Body in Health. By J. D. Bonner, M. D. 364
Heat into Electricity, Direct Conversion of 251
Heating, Electric 294
Heating Houses by Electricity 121, 122
Hercules Electric Motor. Illustrated 46
Hoist at the Black Diamond Mine, Electric. Illustrated 230
Holland, Electric Light in 235
Horse Clipper, Electric. Illustrated 273
Hotel Proprietors, Suggestion to. Illustrated 328
Hubin-LeBlanc Alternating Current Motor. Illustrated 46
Hummel's Motor Meter. Illustrated 361
Hunt Street Generating Station, Cincinnati, O. Illustrated 299

Impression Indicator for Printing Presses, Richardson's Electrical. Illustrated 47
Improvements in Steno-Telegraphy. Illustrated. 63, 64
Incandescent Lamp Litigation 51, 52, 53
Incandescent Lamps, Treating Filaments for. Illustrated 358, 359
Incandescent Lamp Socket. Illustrated 234
Incandescent Lamp Suit Decided in Favor of Edison 32
Incandescent Lighting; Its Physical Hazard and Means for Restricting the Same. By Geo. P. Low 151, 152, 153
Independent—Storage or Primary Battery—System of Electric Traction. By Knight Neftel. And Discussion (American Street Railway Association) 263, 264
Indicator, a Simple. Illustrated 32
Indianapolis, Ind. (Correspondence.) 40, 55, 296
Instrument for Measuring the Strength of Magnetic Fields. Illustrated 8
Insulating Joint, a New. Illustrated 65
Insulating Material, New 379
Insulating or Break Knob. Illustrated 334
Insulator, New Porcelain. Illustrated 65
International Congress of Electricians at Frankfort .. 50
International Congress of Electricians. By Henry S. Carhart 233
Iowa Electric Club 242

Jersey City to Newark, Proposed Electric Road from 36
Jewish Synagogue, Lighting a 199, 200
Joints In Battery Wires, Method of Making Reliable. Illustrated 49

Kankakee, Ill., New Electric Road at. Illustrated .. 87
Kansas City (Correspondence) 337, 365, 380
Keyhole Circuit, a 103

La Boiteaux Fan Outfit. Illustrated 24
Lamp Holder, New. Illustrated 293
Lamp Lighter, Wanted to See the 364
Lamp Shades and Holders. Illustrated 334
Largest Electric Pump in the World. Illustrated 113
La Roche Alternating Dynamo. Illustrated 202
La Roche Arc Dynamo. Illustrated 280
La Roche Special Dynamo. Illustrated 359
Legislation Affecting Lighting Interests (National Electric Light Association) 164
Leonard's, H. Ward, Criticism of F. B. Badt's Handbook. By Thos. G. Grier 146
Lighting Chicago Boulevards 202
Lighting Display, a Chance for a Wonderful. Illustrated 187
Lighting Plant at the Allen Flats, Chicago. Illustrated 47
Lighting the Model City 80
Lightning Conductors, Is "Earth" of Any Value as the Termination of a. By Sidney A. Walker. 194, 195, 196
Lightning in Germany, Statistics of Accidents Caused by 244
Lightning, Protection Against 10
Line Tools, New. Illustrated 36
Liquors by Electricity, Aging. Illustrated 344
Litigaton in St. Louis, Electrical 186
Litigation, Incandescent Lamp 51, 52, 53
Litigation over Accumulators, Patent 66, 67
Locomotive for Mill Use, Electric 236
Locomotive for Mines and Mills, Edison Electric. Illustrated 9
Locomotive, New Thomson-Houston Freight Switching Electric 327
London, Electric Lighting in 359
London, Electric Traction in 120, 121
London's Electric Lights 91
Louisville, Ky., (Correspondence) 55, 366

Magnetic Button Fastener. Illustrated 47
Magnetic Reluctance. By A. E. Kennelly. And Discussion. (American Institute of Electrical Engineers 277, 278, 279, 305, 306
Mailloux Electric Motor, The. Illustrated 100
Maintaining a Constant Potential, Hering's Device for. Illustrated 4
Manchester Square Electric Light Station. Illustrated 150, 151
Masonic Temple, Chicago, Electric Light Plant for the 57
Mathematics, Use of 92
Mather Quadripolar Motor, New. Illustrated 191
Mayo System, The. Illustrated 36
Measuring Electric Currents, Thomson's Method of. Illustrated 64
Measuring the Strength of Magnetic Fields, Instrument for. Illustrated 8
Measurement Apparatus, New Standard. Illustrated 292
Medical Lighting Apparatus. Illustrated 49
Meter, Hummel's Motor, Illustrated 361
Meter, The Grassot Electric. Illustrated 119
Method of Making Reliable Joints in Battery Wires. Illustrated 49
Method of Producing Light by Means of Currents of High Frequency, Tesla's. Illustrated 8
Method of Securing Metal Bands on Wooden and Other Articles, Thomson's. Illustrated 35
Micheles' Device for Avoiding Dead Centers. Illustrated 120
Military Field Telegraph Line, Laying a. Illustrated 32
Mills, Thomson-Houston Electric Tramway for. Illustrated 10

TRADE MARK "K.K."

For Electric Light, Electric Railways, Motors, Telegraph and Telephone Use.

Agents for the WASHINGTON CARBON CO., Carbons for Arc Lighting.

THOS. L. SCOVILL, New York Agent, - - - - 25 Park Place, NEW YORK.

THE INDIA RUBBER & GUTTA PERCHA INSULATING CO.,

—MANUFACTURERS OF—

VULCANIZED INDIA-RUBBER Cables, to any Specification up to 8,000 Megohms per mile.

ABSOLUTELY PURE RUBBER CABLES.

CONCENTRIC CABLES, any millage, FLEXIBLE CORDS. SILK. HEMP. COTTON. DYNAMO WIRES and CABLES. very pliable. Every variety of INCANDESCENT CORES.

HABIRSHAW

RUBBER COVERED

CABLES AND CORES.

THREE and TWO-WIRE CABLES, to any specification up to 8,000 Megohms per knot.

CABLES of High Insulation and Long Life, all milage.

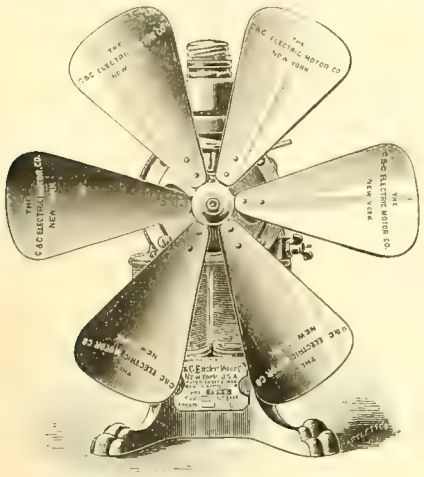
If you are not acquainted with the merits of Habirshaw Insulation we shall be pleased to send you samples upon application.

W. M. HABIRSHAW, Gen'l Mgr. OFFICE: 315 Madison Ave., Cor. 42d St., New York.

FACTORY: Glenwood, Yonkers, N. Y.

WESTERN AGENTS, The Electrical Supply Co., 171 Randolph Street, Chicago, Illinois.

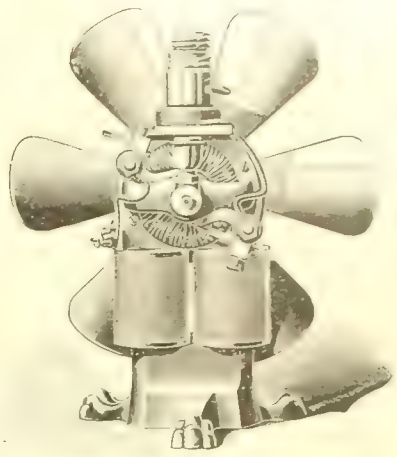
C. & C. FAN OUTFITS.



110 Volt Fan Outfit. Front View.

THE OLDEST AND BEST.

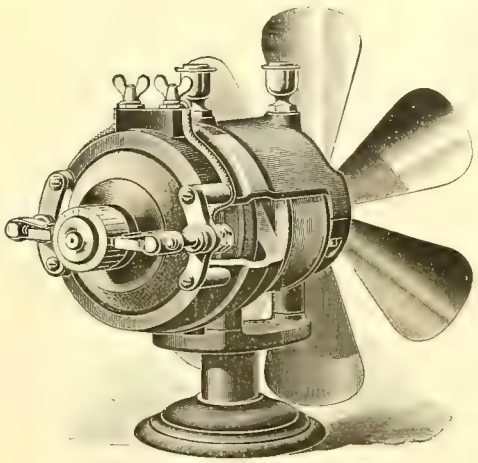
The season of 1891 marks the fifth year since the introduction of the C. & C. Fan Outfits.



110 Volt Fan Outfit. Back View.

Thousands in Operation in Every State and Territory in the Land.

With each season some improvement either Electrical or Mechanical has been made, until the Machine as placed this year on the market, is absolutely without defect.

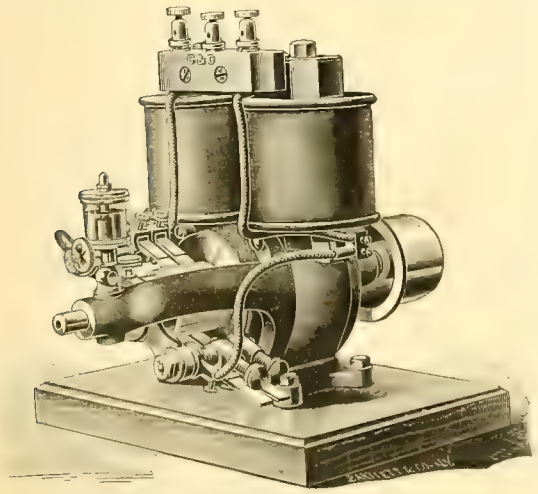


500 Volt Fan Outfit.

Wound for any direct current Circuit.

Finished in dipped brass, polished or nickeled.

For Electric Railway and Power Circuits we are this year ready to supply a Fan Outfit designed especially for high Potential Circuits.



1-4 H. P. Motor for operating Ceiling Fans.

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, uncqualed for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Correspondence solicited from all manufacturers and dealers in electrical machinery and supplies. SEND FOR PRICES AND ESTIMATES.

For Sale by THE CENTRAL ELECTRIC CO., CHICAGO.

To Electric Railway Companies:

We shall be pleased to make you quotations on Washburn & Moen's hard drawn copper trolley wire, and our own make of Weatherproof insulation feeder wires. Our Weatherproof wire is superior to any other wire of like character in the market.

Vol. IX. CHICAGO, JULY 4, 1891. No. 1

Electric Power Transmission Plant at Aspen, Colo.

An excellent idea of the rapid strides that are being made in the application of electricity to mining may be had by examining the electric power transmission plant at Aspen, Colo. This is beyond doubt one of the most interesting electric transmission plants in the United States.

Aspen had been lighted by electricity for four years, the power having been obtained from several small water powers, when, owing to the limited quantity of water flowing in the mountain streams of this region in winter, it became necessary either to put in a steam plant or to use water under a much greater head. The latter course was deemed advisable, and the construction of a plant providing for the use of water under a head of 900 feet was begun about three years ago.

A dam was built on Hunter Creek, about three miles from town. At this point a twelve foot dam creates a reservoir covering several acres of ground. It has been necessary, during a few of the coldest winter nights, to draw upon the supply of water, but the reservoir always refilled during the following day.

From the dam the water is carried about two miles in a wooden flume, buried in the ground, to the head of the pipe line, which is 4,500 feet long and has a fall of 876 feet, giving a pressure of 380 pounds per square inch at the water wheels. Lap welded pipe, fourteen inches in diameter and about one-quarter inch in thickness, is used. This pipe line terminates at the power house, which is shown in Fig. 2.

Here there are eight Pelton water wheels, each two feet in diameter, and each capable of developing 150 horse power. The water wheels run at the rate of 1,100 revolutions per minute and each wheel is belted directly to one or more dynamos. This power has now been in use about three years, and has proved absolutely reliable. The wheels at present operate three 60 light Brush arc dynamos; two 450 light Brush incandescent dynamos, 110 volt direct current; three 750 light Westinghouse 1,000 volt alternators; one 500 volt 80 ampere Edison dynamo, and one 500 volt 160 ampere Edison dynamo. An excellent view of the dynamo room is presented in Fig. 1.

The arc lights are used for lighting the streets and stores; the incandescent lights for stores, residences and mines; the 500 volt dynamo furnishing power to mines.

The power dynamos supply current for driving motors, generally used for ventilation and hoisting in mine inclines.

There are now in use one 10 horse power electric hoist in the Regent mine, one 10 horse power electric hoist in the Aspen mine, one 25 horse power electric hoist in the Aspen mine, one 20 horse power motor running Taylor & Brunton's sampling works and one three horse power motor operating a blower in the Regent mine.

For hoisting purposes motors of the street car type are used, so that the speed is under control of the operator. The motors are connected to ordinary mine hoists by spur gearing and paper friction wheels. These electric hoists are all underground, at points where it would be both difficult and expensive to obtain power in any other way. The distance of the motors from the dynamo is, in most cases, about two miles. Some of the hoists have been running more than three years, and all have proved satisfactory and reliable. The expense for motor repairs has been very small. There are also motors in use for running rock crushers, etc. The motors range in size from three to seventy-five horse power.

The mining engineers in Aspen are wide awake to the great advantages of electric mining machinery. The Roaring Fork Electric Light & Power company and the Aspen Mining & Smelting company have lately contracted with F. B. Badt, manager western power and mining department, Thomson-Houston Electric company, for complete electric percussion drill outfits made by the Thomson Van Depoele Electric Mining company. As the distances in these cases are very great, the Van Depoele direct current motor transformers will be used to transform a direct current of high potential into a pulsating current of 220 volts.

Electric tramways and electric pumps, both for station and sinking purposes [illegible] of the tunnels and shafts.

As already stated, the water power is utilized by means of Pelton wheels. In Fig. 3 is clearly shown the principle of this wheel. The water arriving under high pressure is thrown out of a nozzle against buckets of peculiar shape, Fig. 4, fastened to the outer rim of the wheel. The function of a water wheel, operated by a jet of water escaping from a nozzle, is to convert the energy of the jet, due to its velocity, into useful work. In order to utilize this energy fully the wheel bucket, after catching the jet, must bring it to rest before discharging it, without inducing turbulence or agitation of the particles.

This feature is successfully obtained in the Pelton bucket. Fig 5 shows the jet of water entering and leaving the bucket, under conditions theoretically and practically correct, and, it is claimed, giving a high commercial efficiency to the wheel.

In the plant of the Roaring Fork Electric Light & Power company the power developed is made to conform to the requirements of the plant by the use of reducing tips, so that only as much water is applied as is necessary to run the machinery to which the wheels are attached.

Close regulation is afforded by means of a deflecting nozzle and hydraulic governor attached to each wheel.

Some idea of the enormous power of these wheels, running under the conditions noted, may be obtained from the fact that the weight of the wheels alone is but ninety pounds each. This shows a capacity of nearly two horse power for every pound of weight of material, and, including accessories to make the plant complete, such as shafting, pulleys, boxes, gate, nozzles, etc., the proportion would be four and one-quarter pounds to every horse power developed. The relative proportion in the best type of steam plants would be from 400 to 500 pounds of material to every horse power developed.

As far as the reliability of this power is concerned it is said that the wheels have [illegible] without interruption from any cause since they started, some two years ago. Considering the severe weather en

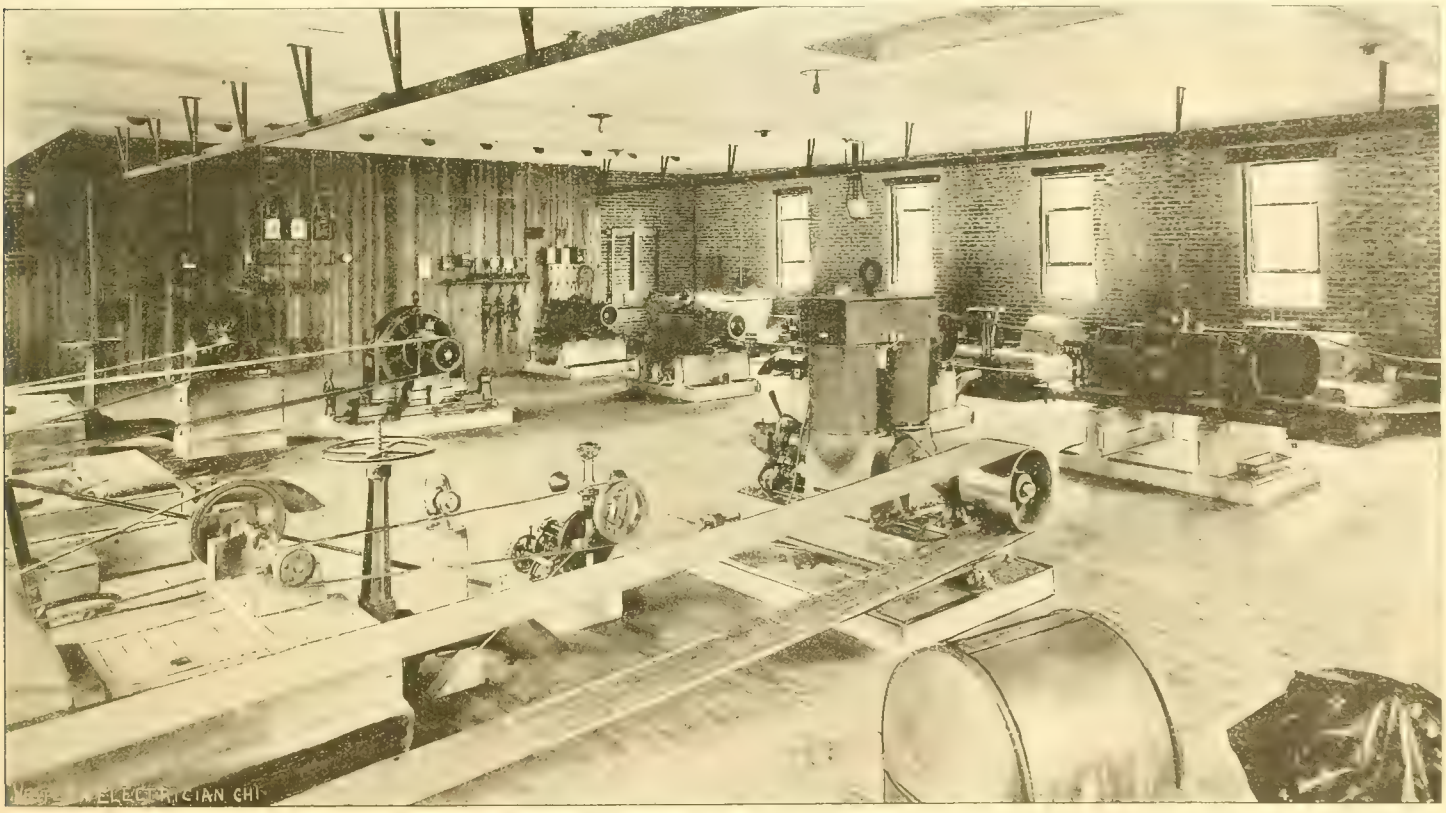

FIG. 1. ELECTRIC POWER TRANSMISSION PLANT AT ASPEN, COLO.

countered at such an altitude during the winter season, [illegible] may be considered quite remarkable. The statement is also made that no interruption of any moment has occurred in the electrical service. Electric power transmission is assuming such dimensions that the water power [illegible] Roaring Fork Electric Light & Power company is all utilized, and the company will put in two Corliss compound condensing engines of 250 horse power each to supply power to customers.

A large number of mining companies at Aspen own their

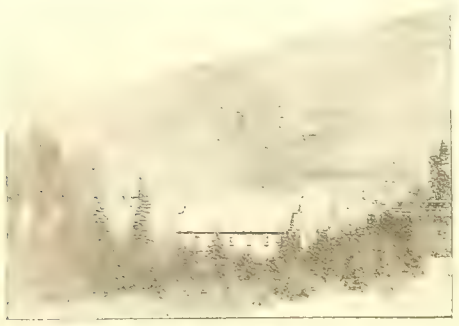

FIG. 2. ELECTRIC POWER TRANSMISSION PLANT AT ASPEN, COLO.

own water power and use Pelton wheels with the best results.

The Aspen Mining & Smelting company has an excellent installation, using two 80 horse power Thomson-Houston 500 volt generators to drive the electric mining machinery, and the Castle Creek Tunnel & Power company, which, under the management of Geo. S. Newman, is just driving a tunnel which promises to be a rival to the famous Sutro Tunnel, has erected one of the finest water power plants in the United States. This company also uses the Pelton wheels. Water power and electricity promise to revolutionize mining in the near future.

The WESTERN ELECTRICIAN is indebted to C. E. Doolittle, superintendent of the Roaring Fork Electric Light & Power company, through whose courtesy the photographs and data were received.

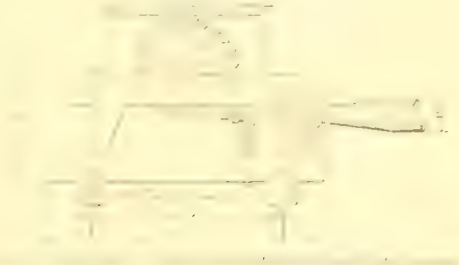
Electrical Department, World's Fair.

Of course the subject of keeping the exposition open evenings is one of prime importance to the electric light interests, and it is one which is engaging considerable attention just now. Chief Barrett is naturally desirous that night displays should be a feature of the fair, and he recently addressed a communication to Director-General Davis setting forth the fact that such displays would form a most attractive characteristic of the exposition, and asking that a definite decision be made regarding the matter.

In conversing on this subject with a representative of the WESTERN ELECTRICIAN General Davis said: "We certainly want to make arrangements for lighting the grounds and buildings at the fair at night. The exposition will be open some evenings—on fete days, for instance—if not on every evening. I have therefore instructed Prof. Barret, acting in conjuction with the Department of Construction, to prepare plans and estimates for the electric light-

It will therefore be seen that, while the matter has not been definitely settled, there is no doubt that electric [illegible] as well as [illegible] lan lscape and water effects, will be a feature of the World's Columbian

No action has yet been taken in contracting for the



*b*uilding as well. Consequently, a second set of bids has been requested.

Engineer Keller, whose appointment was announced in last week's paper, has taken charge of his work at the Department of Electricity.

Elisha Gray, the veteran inventor, writes from Highland, Ill., to say that he desires 10,000 square feet in the electrical building at the World's Fair to display his inventions. "I desire my application to be somewhat flexible," he says, "for I hope to have one or more new things ready to exhibit by the time the exposition opens." Mr. Gray will exhibit hotel signals, musical and speaking telephones, telegraphic apparatus and his latest production, the telautograph.

Recent Developments in Electric Mining Apparatus.[1]

BY J. W. KIRKLAND.

No other section of this continent offers such exceptional and striking facilities for the introduction of electricity as does this great province of Quebec. Nature has been bounteous in her distribution of water, and your hills have, by their ruggedness, forbidden these masses of water from pursuing a slow and unbroken course to the sea. In traveling through your country the visitor from the United States is impressed by the fact that there is hardly a town, hardly a mine, hardly a factory, which is not almost within hailing distance of some river or torrent which has for ages been expending its kinetic energy in re-arranging its chan-

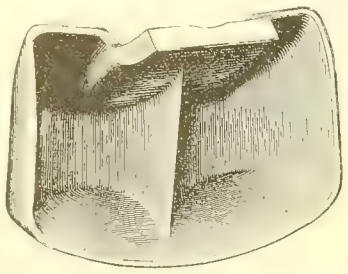


FIG. 4. ELECTRIC POWER TRANSMISSION PLANT AT ASPEN, COLO.

nel and cutting away the rock over which it flows. These waterfalls are destined to become the great agency for opening your mines and driving your mills, and for transporting their joint products. So much for the water facilities; but we may still go farther in congratulating you upon your possessions of cheap power. Even where water power is not at hand you are still more advantageously situated than are your neighbors, with your great woodlands waiting to be cleared in order that better things may be planted, and in the clearing supplying cheap fuel for your boiler fires.

In connection with the development which is bound to

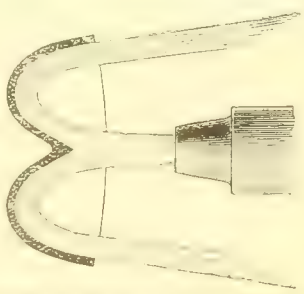

FIG. 5. ELECTRIC POWER TRANSMISSION PLANT AT ASPEN, COLO.

spring from these great natural bequests, one fact is assured; one powerful agent, electricity, must play an important part. The strides in its application have been tremendous in the last few years; the prophet who will not foretell still greater advances is faint-hearted indeed.

An electric mining equipment consists of three elements, each to be considered separately and each forming a distinct part of the problem to be solved. They are, the generating plant, the line, and the motor or other device for utilizing the current. The generating plant, which comes first, from its very nature, differs but very little from electric lighting installations, already so common, the dynamo electric machines having, however, a rather different form. The [illegible] and protective devices, consist of the usual ground and potential indicators, the lightning arresters, the [illegible] the [illegible] cut-outs, the desirable position of which and the method, connection are often pre- [illegible]. The generators are, as a [illegible] for [illegible] potential of 220 volt this seem [illegible] become one of the standard units [illegible]

of electric pressure by reason of the fact that the incandescent lamp is conveniently made for a pressure of 110 volts, so that upon 220 volts two incandescent lamps may be run in series. The pressure chosen is one which is perfectly harmless to either human or animal life. It admits of very perfect insulation in the underground chambers of mines, which are, as a rule, impregnated with moisture which is always seeking to form a by-path for the electric current. The generating station requires primarily a source of power,

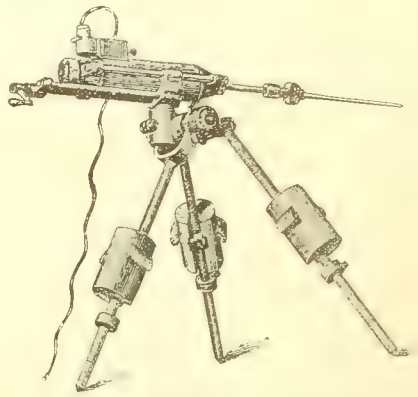

FIG. 3 RECENT DEVELOPMENTS IN ELECTRIC MINING APPARATUS.—VAN DEPOELE ELECTRIC PERCUSSION DRILL.

whether of water or steam, and its position with reference to the mine is therefore determined principally by the condition of obtaining power cheaply and conveniently. It may be several miles from the mine or quarry; it may be in the quarry; or again it may be at the bottom of the mining shaft, as is the case in a somewhat celebrated plant in the Comstock Lode.

The line is so simple a feature as to require no description. You have your poles close at hand, generally needing but a few strokes of a woodman's axe to prepare them for their work; your wire and supplies you can buy cheaply right here in Canada.

Having brought your power to the mine, the ways in which you can dispose of it are almost without limit; with it you may displace your ponderous steam pump, your costly air compressor, your steaming, sweating, and, worse still, short-lived mules; and last, but not least, your dangerous miner's lamp. With it you can ventilate the most remote corner of your workings, and the shaft which has previously been useless because mother nature has chosen it as an artery for her watery blood becomes, by the introduction of an electric pump, a dividend-paying property.

I will call your attention to the form of drill invented by Chas. J. Van Depoele and manufactured by the Thomson-Van Depoele Electric Mining company. This photograph (reproduced in Fig. 1) shows the drill as it appeared in a practical test made at the quarry of the Cape Ann Granite company, Cape Ann, Massachusetts, a few months ago. The rock drill which is represented in the cut has a capacity to drill a hole two inches in diameter in the hardest kind of granite that we were able to obtain for the test at the rate of something over 1½ in. per minute, and this with an expenditure of only about 2½ electrical horse power. The coils and connections, the carriers of the power-giving current are completely inclosed within a solid iron casing and are simple in the extreme, a quality which should be one of the very first to be sought in designing all mining machinery, whether electrical or otherwise. A cable consisting of three separate insulated conductors of small

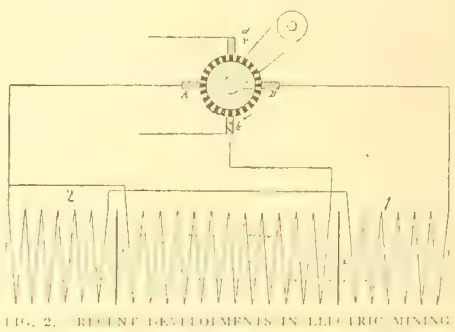

FIG. 2. RECENT DEVELOPMENTS IN ELECTRIC MINING APPARATUS.—VAN DEPOELE ELECTRIC PERCUSSION DRILL.

cross-sections is connected to corresponding terminals in the junction box at the top of the machine. This diagram, Fig. 2, which has been prepared from the patent granted to Mr. Van Depoele on his invention, shows the three wires running from the dynamo D and the three coils or solenoids within the drill. The central coil is traversed by a current pulsating in intensity but constant

in sign or direction, which serves to keep the iron core or piston in what is electrically termed a saturated condition—that is to say a state of maximum magnetization at all parts of the stroke. It is termed a polarizer, and consists of many turns of small wire. One terminal of this coil is connected to one of the revolving brushes and the other to a stationary one which is in this case the negative. The current, therefore, in this coil varies from zero to maximum and back again to zero, as the brush *A* moves from the position in line with the negative brush all round the commutator and back to its original place. Let us examine the coincident conditions in the outside coils, first stating that these are of few turns of comparatively large wire, and so that if a north pole is at any instant at the inside end of the upper coil, marked number 1, a similar pole finds itself at the corrresponding extremity of the coil number 2.

The polarizing coil is energized by a current produced by the difference of potential between the brushes *A* and *b* equal to one-half of the voltage of the dynamo—or 110 volts. At this instant the outside coils are neutral because the brushes *A* and *B* are at their middle points, and the core is now drawn towards the middle of the drill, lagging behind the magnetism an appreciable amount.

Assuming now that one-quarter turn of the yoke holding the revolving brushes has been made, the middle coil is now getting its maximum current due to the total electo-motive force of the dynamo; the outside coils are also at their maximum, and while one is tending to repel the similarly magnetized core in the direction of the coil, the latter is itself at the same time exerting an attraction upon the core. Another one quarter turn and the current in the outside has waned and disappeared entirely, and the current in the polarizer has also decreased to one-half its maximum value. Another one quarter turn and the conditions are the same as those when the brush *R C* was in line with the positive terminal, except that the direction of current in the two outside solenoids is at present of opposite sign. The core is therefore pulled toward the other extremity of the drill. This action is repeated continuously, the magnetized core always seeking to place its north pole as close as possible to the nearest pole of opposite sign, that is, it tends to embrace at each instant the greatest possible number of lines of force, or in lay terms, magnetism.

From this I hope that those of you who have not neglected your electrical education will see why the core is kept vibrating, making one stroke up and down for each complete revolution of the revolving brushes. The length of the stroke depends upon the rate of pulsation and upon the distance of the drill from the rock it is cutting. Fig. 2 is another view of the drill familiar to some of you. The motion is imparted to the revolving brushes by means of a small intermediate shaft, belted to a sliding yoke which revolves close to the commutator and carries brush-holders at its two opsite extremities It may be well to state that an automatic device consisting of a steep pitched screw and nut gives the drill a turn of one-eighth of a revolution at every stroke, thus insuring a clean-cut round hole. The same form is at present made in three sizes. These drills are also, when required, placed upon quarry bars for mine and tunnel work.

Before leaving reciprocating apparatus entirely, it will be well to touch upon a machine similar in principle to the drill, viz., the reciprocating pump, in which the power end resembles in outward appearance the corresponding end of a steam pipe, but which, instead of containing a carefully turned cylinder with close fitting piston and steam valves and joints, contains essentially the same arrangement of solenoids as I have described in connection with the rock drill. The pump is light and compact and lends itself readily to use in sinking shafts, where space is of much importance, and where it is necessary to suspend the pump vertically and lower it by means of chains as the work progresses. A pump of this kind having a water cylinder of 4 by 8 inches, built by the Knowles Pump company, Warren, Mass, is now in Frankfort, Germany, at the great electrical exhibition. The results obtained from its tests may be of interest. I quote directly from the report of the expert in charge: "Weight complete on base, about 800 pounds; weight of motor end, 400 pounds; strokes per minute, 120; horse power consumed, about 2½ or 3; gallons raised per minute, 50; head, 100 feet. The water piston was so tight that it could not be moved by hand, so that a good deal of power was thus absorbed. After a day or two of continuous working this difficulty will be removed."

Passing now from electrical apparatus in which the magnetic attraction is exerted to produce rectilinear motion, let us turn to those in which the electric motor in its usual form delivers its energy by a rotary motion.

FIG. 1. RECENT DEVELOPMENTS IN ELECTRIC MINING APPARATUS.—VAN DEPOELE ELECTRIC PERCUSSION DRILL.

Mine traction is one of the first problems to be solved, and happily it is one to which electricity is peculiarly well adapted. A new design of mining locomotive of a capacity of 60 horse power is being built for the Blossburg Coal company, operating the Bear Run mine in Pennsylvania.[1] Another of the same size is under construction for the Hillside Coal & Iron company, another of 40 horse power is to go to Schofield, Utah, and a fourth of 25 horse power to the Livingstone Coal & Coke company, Livingstone, Montana.

The mechanism is inclosed completely in an iron covering which prevents the admission of water and protects the moving parts from injury which might be caused by falling rock or careless workmen.

This machine weighs, complete, about 21,000 pounds; it has an estimated traction of 2,000 pounds, at 10 miles per hour, and will haul a load of 85 tons at a speed of 10 miles per hour on a level. Its height over all is only 40 inches and its gauge is 36 inches up. The 60 horse power motor is carried directly upon the axle of the machine, and is reversible. Its speed and traction are under the immediate

[1] This machine was illustrated in the WESTERN ELECTRICIAN of July 5, 1890.

frame and platform, and in strengthening all parts. In this respect [illegible] the weight is too often supplied by attaching otherwise useless masses of iron to the platform.

[illegible] vided for the overhead wire which guides the trolley wheel in the proper direction.

It is not an unusual occurrence in mines to find steep grades of more or less length, which, if they were to be surmounted by the locomotive, would require that it be of large capacity for hauling ordinary loads on level stretches; to do this work by such machines would therefore be uneconomical. [illegible] beg to call your attention to the electric hoist (see WESTERN ELECTRICIAN, page [illegible]) rope haulage upon the grades is operated, running [illegible] and doing the work of a locomotive in raising the cars. This hoist consists of an especially designed motor, waterproof in construction, [illegible] one bedplate with a hoisting drum, and geared to it through a friction clutch. This motor is like the one used in the mining locomotive, reversible, and its speed controlled by a rheostat. A strap friction brake is applied by a foot lever. This clutch is operated by the hand lever, and the rheostat and reversing switch are manipulated by a third lever. The whole machine is compact and simple, having few moving parts and requiring no skilled labor for its operation.

The following are some figures upon the 15 horse power hoist: Total weight, 1,435 pounds; speed of motor, varying between 700 and 1,200 revolutions per minute; speed of winding drum, varying between [illegible] revolutions per minute; efficiency of the hoist, 60%.

When you consider that this figure of efficiency takes into consideration all the mechanical and electrical losses, such as friction of gears and of rope, you will I think, admit that it is high.

I leave it to you as practical men to weigh [illegible] tric hoist against the steam hoist with all the small details of piping and valves which the name implies, and I feel certain that the latter will be found wanting.

The electric hoist is, moreover, a probable successor to the steam winch at the top of the mine shaft, used for raising cars and buckets.

Montreal Convention.

Secretary Beane of the National Electric [illegible] ation writes enthusiastically of the coming Montreal convention. He says that [illegible] papers on subjects have been promised from [illegible] C. Warren of Chicago, Captain [illegible] H. Ward Leonard of New York, Prof. Weston, C. J. Field of New York, [illegible] Buffalo, William Stanley of Pittsfield, [illegible] Tesla has also promised that [illegible] time, he will give an evening [illegible] recent researches.

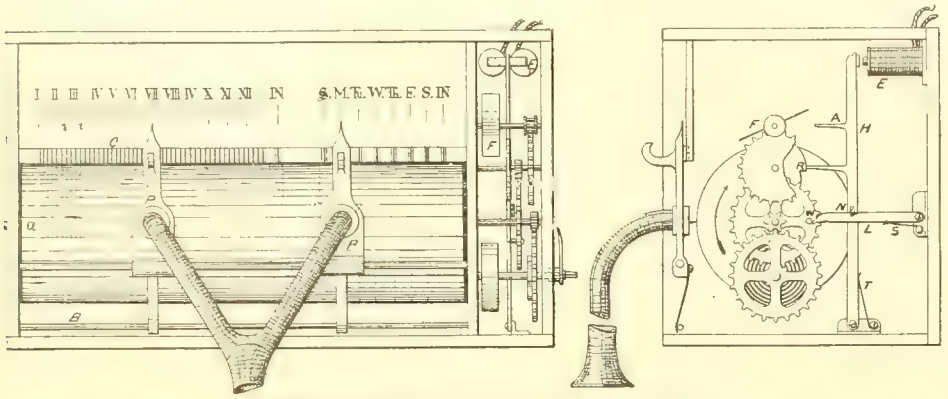
The American River Syndicate of [illegible] Cal., will operate a [illegible] by a 25 horse electric motor. This company now has a 100 horse power Brush generator, and a [illegible] Electric power will also [illegible] pumping works.

Phonographic Telephone Signaling Apparatus.

The accompanying cut is a front and end view of a novel telephone signaling instrument designed so that it may be set so as to automatically send back through the telephone most any verbal message that it is desired to dispatch to those ringing up a subscriber during his absence. It is also claimed for the device that it may be made to register the number of calls made at the telephone, and that by mutual agreement between users of telephones, the number of times the telephone is rung up may constitute a signal showing the importance of the call that has been made at the telephone.

The apparatus is a combination with the telephone, of a phonograph and a mechanism of such construction that the ordinary "ringing up" signal starts the phonograph, and a spring operates and automatically stops it.

The arrangement of the clock-work in connection with the phonograph will be readily understood from the illustration. Before explaining the operation, however, the indicating portion of the apparatus must be described.



PHONOGRAPHIC TELEPHONE SIGNALING APPARATUS.

Two pointers, *PP*, are fitted on the horizontal bar *B* so that they may be easily moved along and made to point to any particular set of the letters or figures. The row of notches, *C*, keeps the pointers exactly in place.

The surface of the phonograph cylinder may be considered as being divided into three portions. Upon the portion to the left, parallel and vertically arranged lines of words are impressed as indicated by the dotted lines *a*. For instance, the one of the lines which is nearest to the end of the cylinder may contain the words "One o'clock," or 'Out till one o'clock." The next line will say "A quarter-past one." The third line will say "Half-past one." The fourth line will say "A quarter to two," and the next succeeding line will say, "Two o'clock;" and so on with all the hours and quarters of the hours shown by the clock.

Upon the portion of the cylinder to the right on the opposite side of the cylinder, the hours are indicated by the dotted lines *b*. Upon the middle portion of the cylinder, the minutes are indicated by the dotted lines *c*. The cylinder is rotated by the mainspring, *S*, which is connected in the circuit of the telephone, so that when the telephone is rung up the signaling current magnetizes it. This moves lever *H*, so that its arm *A* releases the fan *F* and permits the mainspring to revolve the gear-wheels and the phonograph cylinder. The arrangement of the instrument is such that for every pull of the magnet the cylinder will make just one revolution and then stop automatically until the telephone is rung up again. This action will be understood from the following description: The lever *H* when attracted by the magnet swings on its pivot till its pin *N* engages with the notch in the lever *L*, which is constantly forced upward by the spring. When the ringing of the telephone bell ceases, the magnet lets go the lever *H* and the spring *T* will drive the arm *A* of the lever *H* into a stopping-contact with the fan. To prevent the latter movement from taking place before the roller has made one revolution and to secure just one revolution of it, the engagement of the pin *N* with the lever *L* is depended upon to retain lever *H* near the magnet until the pin *W* engages with the free end of the lever *L*, and swings the notch away from the pin *N*. This done, the lever *H* is so far at liberty to swing back and engage with the fan *F*, but, as this would stop the instrument, the circular edge of the cam *R* holds in place the lever until pin *W* has passed the free end of the lever *L*, when the arm *A* reaches the fan and stops every part of the instrument in the proper position.

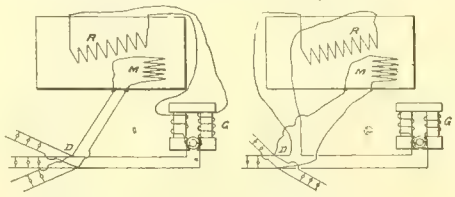


FIG. 2 AND 3. HERING'S DEVICE FOR MAINTAINING A CONSTANT POTENTIAL.

Hering's Device for Maintaining a Constant Potential.

The difference of potential of a dynamo, or at the poles of incandescent lamps supplied by a dynamo, is dependent the armature, the variable amounts of current, the resistance of the leads, the position of the brushes, and in shunt or compound wound machines the heating of the field magnet coils.

The object of the device illustrated diagrammatically herewith, which is an invention of Carl Hering of New York, is to automatically compensate for the effects of such irregularities in the difference of potential and thus maintain the difference of potential constant.

The regulator, Fig. 1, consists, essentially, of a "detector" and an adjustable resistance. The object of the former is to detect any changes, and when they exist to adjust the resistance. This resistance is so connected with the circuit of the machine that it will control the difference of potential at the points where it is to be kept constant.

The apparatus, Fig. 1, may be connected into the circuits of a shunt-wound machine, as shown in the diagram of connections, Fig. 2. *G* is the shunt wound generator feeding a system of lamps from a center of distribution *D*. The coil *M* is connected to the point *D*, where the potential is to be kept constant. The resistance R is placed in the shunt-magnet circuit. Should the potential at *D* rise or fall, the detector will increase or decrease the resistance *R*, which in turn will vary the field current accordingly, which will again adjust the potential. The coil *M* is connected to the center of distribution, in order that it may correct for variable losses of potential in the leads. When the changes of potential are so rapid that the magnetism of the field magnet does not respond quickly enough on changes of the resistance *R*, or when the generator is a battery, the resistance is connected directly in the main circuit, as shown in Fig. 3. This method is especially applicable to lighting from storage batteries or to dynamos driven by gas engines or other engines whose speed pulsates rapidly.

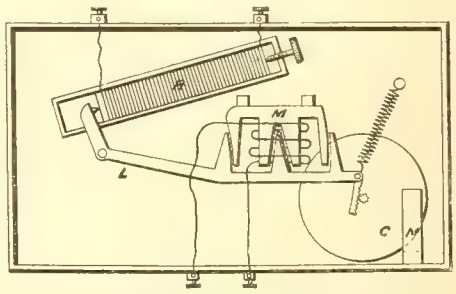

FIG. 1. HERING'S DEVICE FOR MAINTAINING A CONSTANT POTENTIAL.

The electro-magnetic damper *C N* may be attached to prevent too rapid motion. This latter device consists merely of a copper disk geared, as shown, to the lever and revolving between the two poles of a U shaped magnet. When the lever moves currents are generated in the disk and the motion is retarded.

It will be noticed that the detector magnet *M* is of peculiar design. This construction was employed to obtain a magnet of "long pull."

In Fig. 3 is shown an improved arrangement of the same device, through which, it is claimed, a magnified effect may be secured. In this arrangement, as will be seen from the diagram, a relay is introduced.

[illegible] CITY'S RAILWAY [illegible] THE EFFECT.

Sioux City's New Railway.

Probably the new electric line at Sioux City, Iowa, which was formally opened with much enthusiasm on the 19th of last month, may claim the honor of being the most picturesque electric railway in the country. At least everybody in Sioux City thinks it is, and all visitors have come away impressed with a similar idea—a view borne out by the glimpses of the line shown in the accompanying illustrations.

The road, which is known as the Riverside Park railway, is about nine miles in length, beginning at the center of Sioux City and terminating at North Riverside. The lat-

SIOUX CITY'S NEW RAILWAY.—THE DEEP CUT.

ter suburb contains a large number of factories and is evidently destined to be a manufacturing center. In addition to the main line traffic, the company is building up a large business in carrying people to Riverside Park. This beautiful pleasure ground contains about 400 acres and lies along the Sioux river, which here separates Iowa from South Dakota. Good boating facilities abound, and the railway company owns several steam launches and about one hundred row-boats.

Starting at the center of the city the line is double-tracked to Floyd creek, from which point the remainder of the road consists of single track. The overhead construction consists of single poles on one side of the track, with brackets supporting the trolley wire. Although the line has some thirty-eight curves, ranging from four to twenty degrees, yet it was found unnecessary to use curve brackets or curve appliances, the special trolley hangers being sufficient to admit the trolley wire conforming to the alignment of the track.

Owing to the nature of the ground cuttings and fillings are frequent. From fifty to one hundred thousand yards of earth were removed and filled in, in building the line. Beautiful bits of scenery, with here and there river glimpses, can be found at every turn, and the road [illegible] to achieve popularity if scenic attractions can assure it. The pictures give a better idea of this. The long trestle is one of the most prominent objects encountered in a ride over the line. It is 634 feet long, having a 19 curve of 300 feet and a rise of four per cent. The upper end of the trestle is 34 feet above the Chicago, Milwaukee & St. Paul track, which is seen passing underneath. On the right of the illustration is a corner of the power house, beyond which is the confluence of the Sioux and Missouri rivers. The view afforded while riding upon this trestle is very fine. The excavation in the "deep cut," also shown, is 70 feet deep.

The power house is located at Riverside. It is a brick building 62 by 95 feet. The steam plant, furnished by Westinghouse, Church, Kerr & Co., consists of Worthington pumps, Krochell heater, Hancock inspirators, four sets of steam loops and two Westinghouse compound engines of 125 horse power each. The engines are belted directly to two 100 horse power Westinghouse generators, which are run at 300 revolutions per minute. The switch-board is polished sycamore with marble face, on which are placed all the instruments necessary for manipulating the three circuits.

The car house is situated a short distance from the power station. It is 50 by 150 feet and contains four tracks the entire length of the building with ample pit room. An elaborate system of car switches is laid out in front of the car house, switch signal lights being used on this line, which is run on steam railroad principles.

Two 30 horse power Westinghouse motors are mounted on each motor car. A speed of twenty-five miles an hour was easily attainable, and later on, when the cars get limbered up and the track is in better condition, higher speed than this is confidently expected. The six motor cars and six trailers were built by the Northern Car company at Minneapolis. The motor cars are vestibuled and very handsome. Their length over all is 36 feet. The trail cars, which are open, are of similar length, and have seating capacity for 78 persons. The trucks for these cars were furnished by the McGuire Manufacturing company of Chicago and are of their latest pattern, designed for the high speeds required. All the overhead material was furnished by the Electric Merchandise company of Chicago.

B. F. Jones, electrical engineer for the Westinghouse Electric & Manufacturing company, had entire charge of the electrical installation, and he performed his work in a most satisfactory manner. The line is well built and well equipped.

After the formal opening, J. Livingston Barclay and J. M. Atkinson, representing the Westinghouse company, entertained at the Hotel Garretson the gentlemen interested in the road, representatives of the press and several visitors. Among those present were President Chas. W. Hornick, Secretary England of the Electric Merchandise company B. F. Jones, C. F. Dodge, C. F. Coombs and others.

Order of Railway Telegraphers.

In a [illegible] this paper as chosen at the St. Louis convention of the [illegible] to serve on the grand executive committee are D. G. Ramsay, St. Louis; A. [illegible] Indiana; [illegible] tucky; F. R. Eckhard, Illinois, and J. M. Clark, Texas. Through his position as assistant grand chief, Daniel G. Ramsay of St. Louis is the chairman of the grand executive committee. It was decided to hold the next convention in Chattanooga during the second week in May, next year. The insurance features of the order were abolished altogether.

SIOUX CITY'S NEW RAILWAY—[illegible] AND ST. [illegible]

The constitution embodying the protective or strike clause having been unanimously adopted, but little opposition was expected to the proposition to federate the Order of Railway Telegraphers with the Federated Order of Railway Employes. The grand chief telegrapher, in calling the matter up for final action, said that most of the time of the convention had been given to discussion on this matter. In the discussion that followed and in which many members took part, it was asserted that the railway corporations were [illegible] protection clause, permitting strikes, the order would be useless. With the strike clause in their constitution, and their order affiliated with the other skilled labor of the railroads, they would be greatly benefited. When the result of the ballot was announced it was found that all but six members had voted for federation. The grand secretary was instructed to apply at once to the Supreme Council for admission to the Federated Order of Railway Employes. The result of the vote on federation was loudly applauded, and the convention adjourned with enthusiasm.

Wilhelm Eduard Weber's Death.

A cablegram received last week announced the death of Wilhelm Eduard Weber at Goettingen. The accompanying portrait and sketch of the eminent scientist is taken from "Derivation of Practical Electrical Units" by F. B. Badt

Wilhelm Eduard Weber was born at Wittenberg, October 24, 1804 In 1831 he was professor of physics at the University of Goettingen, and in 1843 was professor at the University of Leipzig. In 1849 he is found again at the University of Goettingen. He published, with Gauss, in 1836-'41 the results of observation of the Magnetic association. In 1840 he published the "Atlas of the Earth's Magnetism." From 1846 to 1878 he compiled "Electro-Dynamic Measurements." In this latter work Weber introduces the system of absolute units.

In the earlier stages of the science several units were introduced for the measurement of quantities dealt with in electricity. In illustration may be mentioned the wire of Jacobi (25 feet of copper wire weighing 345 grains), the mercury column of Siemens (1 meter long with a section of a square millimeter), which at given temperatures furnished units of resistance, and the Daniell cell, which furnished the unit of electromotive force. Jacobi's current unit was based on the electrolytic decomposition of water. One cubic centimeter of oxy-hydrogen gas is formed each minute. All these units were perfectly arbitrary, and there was no connection of any kind between them. The introductionof a rational system of unitation, based on the fundamental units of time, mass and length, was one of the greatest achievements of modern times. The impulse came from the famous memoir of Gauss, "Intensitas vis Magneticæ Terrestris and Mensuram Absolutam Revocata," in 1832. In conjunction with Weber, he introduced his principles into the measurement of the earth's magnetic force.

To Weber belongs the credit of doing a similar service for electricity. He not only devised three different systems of such units—the electro dynamic, the electro-static and the electro-magnetic, but he carried out a series of measurements which practically introduced the last two systems.

The practical units which are in use to-day are simply certain multiples of the absolute or Centimeter-Gramme-Second (C. G. S.) units. The absolute units are either too great or too small for practical use, and for convenience the "practical units," were adopted, to which the names of the most famous electricians are given.

Weber was the most illustrious among the successors of Ampere. He greatly improved the construction of the galvanometer and invented the electro-dynamometer. To these instruments he applied the mirror scale and telescope method of reading, which had been suggested by Poggendorf and used by him and Gauss in magnetic measurements about 1883. In 1846 he tested by means of his improved apparatus the fundamental laws of Ampere. The result of his researches was to establish the truth of Ampere's principles, as far as experiments with closed circuits could do so, with a degree of accuracy far beyond anything attainablewith the simple apparatus of the original discovery. Applying his improved instruments he alsoobtained accurate verification of the laws of induction, which by this time had been developed mathematically by Neumann and himself. The experiments of Weber must be considered as experimental evidence establishing the theory of Ampere and as such they form one of the corner stones of electrical science. Clausius and Siemens proposed the term Weber for the practical unit of the strength of the magnetic pole. This unit is equal to 10^8 C. G. S. units. The term has not yet been generally adopted as a practical unit. The term Weber was formerly employed to designate the unit strength of current. This term is now replaced by the ampere,

Rapid Transit for Detroit.

The city council of Detroit, Mich., and the street railway companies last week held a conference regarding the problem of rapid transit. Several ordinances have been before the council. These ordinances are alike in providing for an extension of the franchise to 30 years, and in requiring the adoption of "cable, electric, or other mechanical power, including steam," in lieu of animal power. An exception is made of Woodward avenue, on which, in accordance with the wishes of the Woodward Avenue Improvement association, the cable system is specified. Mr. Currie read the ordinance to the committee, saying that the Jefferson avenue line, already having the heavy rails, would be equipped within six months, with the overhead wire system, if the ordinance should be adopted, and if the Woodward avenue people like it, then there would be time for the council to amend the ordinance, if desired, and sale [illegible] The company would be willing to accede to the change any time before the contract for the cable line may have been signed. The companies may desire to extend their lines in many directions, and establish new lines. They express a willingness to do this and give first-class service, introducing the electric system on all their roads, provided their franchises are extended 30 years.

The Grand River avenue street railway ordinance prescribes the overhead wire system, provides for a double track on Myrtle street, does away with one track on Woodward avenue north of Fort street, and extends its track from its present terminus at Jefferson avenue to the foot of Woodward avenue. The tracks on Woodward avenue shall be used by the Detroit City railway and the Grand River avenue railway in common.

The Fort Wayne and Elmwood company's proposed ordinance provides for a double track on Champlain street, from Mt. Elliot avenue to Van Dyke avenue, and also on Fort street west from Clark street to the westerly limits of the city.

In all cases the maximum speed is to be 20 miles an hour, so that in the business portion of the city the cars may run slowly and yet average 10 miles an hour.

Electric Wires in Rochester, N. Y.

Attention has heretofore been called to the effort being made at Rochester, N. Y., to compel the electric companies to bury their wires. The committee on electricity of

WILHELM EDUARD WEBER.

the city council and City Electrician Barnes have taken the matter up, and last week there was a conference between the representatives of the city and the electrical companies. It is believed that something will come of the present agitation, as much interest is manifested. Those who recollect the "late unpleasantness" between the telephone company and its Rochester subscribers will be inclined to believe that the present movement will be continued and may possibly give the electric companies considerable annoyance.

City Electrician Barnes says that the electric system of Rochester has been so greatly developed that a standing committee of the council has become necessary to supervise it. He called attention to the interference with the successful working of the system caused by the induction from the electric railway wires. He suggested that metallic circuits would remedy this trouble.

Frank J. Amsden, secretary of the old Citizens' telephone committee, which conducted the war on the Bell company, appeared before the conference and said he had heard numerous complaints. The committee looked to the council to afford some relief. In 1888, he said, the telephone users had agreed to pay a certain rental rate for a good service He knew that metallic circuits would cost much money, and make rentals somewhat higher. He believed that some arrangement could be made between the company and the users of the telephones, and that the latter might be willing to pay a small increase.

George Weldon, a director of the telephone company,

[illegible] wires and to make it a misdemeanor to interfere with or take down wires

[illegible] says: "Since the extension of the system of electric lighting and the introduction of the new street car service, the danger to persons and property from the overhead wires has been increased greatly, and there can be no doubt of the necessity for careful supervision of all electrical systems by the authorities. Wires of all kinds have been strung about the city, in some instances carelessly, without proper consideration for the safety of human life, and in disregard of existing laws. Some of the telegraph and electric light poles are rotten and liable to fall at any moment; and in the aggregate, there are miles of "dead" wires—none of them of any use to the companies that put them up, and all of them a constant source of danger.

"It would be fortunate if all telephone, telegraph and electric light wires could be put underground, particularly in the business portions of the city. They are not only unsightly and dangerous, but are great impediments to quick and effective work by the fire department, for they must be cut before ladders can be placed against the sides of burning buildings. The electric light companies say no satisfactory system of underground conduits for their wires has ever been devised; but we think the experts can put the wires below the surface of the streets and make them work all right if enough money is furnished. At any rate, this is a question to which the committee ought to give its careful consideration, making investigations in other cities, and employing experts of its own.

"Great improvements are possible in the telephone service. Ever since the electric cars began running the telephones have worked very unsatisfactorily on account of the induction.

"Of course, the construction of metallic circuits would be a heavy expense to the telephone company; but the service would be infinitely better, and the people would be willing to pay higher rentals. Not only that, but many persons who refuse to use telephones now because of the poor service would put them in; so that, in the end, the company would be better off in every way."

Proposed New Chicago Electric Road.

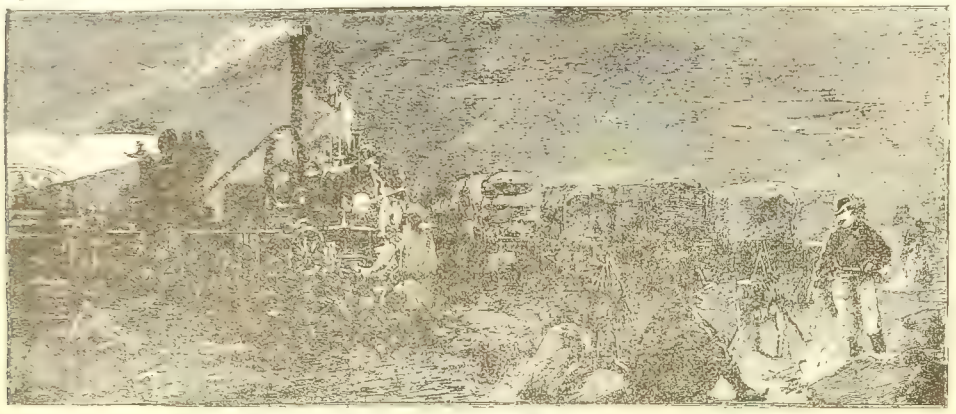
An ordinance giving a franchise to the Calumet Electric Street Railway company was introduced at the last meeting of the common council of Chicago. The ordinance is a most comprehensive one, as it is proposed to occupy nearly every important north and south and cross street in that part of Chicago south of Eighty seventh street with an electric road track and provides for a loop extending from Eighty-seventh street along South Chicago avenue and Stony Island boulevard and Sixty-seventh street, bending westward on the latter thoroughfare to Cottage Grove avenue, and thence south on that street to Eighty-seventh street, with a cross-section on Eighty-seventh street. It is thus intended to bring the extreme southern and eastern sections of the city from the Indiana state line and Fernwood up to the gate of the World's Fair. At least one line of track is to be in operation within eighteen months. The overhead trolley system is to be used. The ordinance, which is accompanied by a petition of the owners of abutting property on the several streets, was referred to the committee on streets and alleys south, and the petition was referred to the commissioner of public works for verification. The promoters of the road are now the owners of a few miles of electric road in the Calumet region, who are interested in the development of the Chicago Canal and Dock company's property. At the head of the number are Columbus R. Cummings, Sydney Kent, W. B. Howard, Douglas [illegible]

A new electric light company has been incorporated in Pana, Ill., with a capital stock of $50,000. The company will operate an [illegible] incandescent lighting [illegible] street railway line.

A Washington dispatch [illegible] electric lighting apparatus for [illegible] and Texas, building at the Brooklyn and Norfolk navy-yards, were as follows: Edison General Electric company, New York—Generating sets, [illegible] closing spare parts, $[illegible] $11[illegible] company, Boston—Generating sets, $60,000; ditto, including spare parts, $[illegible] signal apparatus, $[illegible] about five months.

The Electric Light in the Service of the African Explorer.

In October, 1889, the charter granting the British South Africa company permission to occupy Mashonaland was signed, and immediately afterward steps were taken to raise a body of men to cut the road from the Macloutsie river, in Bechuanaland, to Mount Hampden, in Matabeleland. The whole force, inclusive of 180 men called the pioneer corps, numbered about five hundred. In April, 1890, the pioneers left Cape Town and made a short stay at Kimberley, where a portable six-horse power engine was taken off its original carriage and was built into a Cape wagon. The engine was used to drive a dynamo for an electric search light of 10,000 candle power, of the naval pattern, placed upon a stand high enough to throw its rays all over the country; for it was generally supposed that if the column were attacked by the Matabele they would get as close as possible by night, and at daylight would rush the camp.



THE ELECTRIC LIGHT IN THE SERVICE OF THE AFRICAN EXPLORER.

The Tuli river was reached without mishap in June. At this place a strong position was taken up; the machine guns and seven pounders and the search light were taken to the top of a commanding hill, and the camp was formed immediately beneath. Every precaution was taken and the column rested here some few days. On September 12th the pioneers arrived at their destination. Here another fort was built, and on September 30th the column was disbanded.

The illustration, which is a view of the search light as used at night at the camp near the Tuli river, is from a sketch made for the *Illustrated London News* by Lieutenant W. Ellerton Fry of the pioneer corps.

Tesla's Method of Producing Light by Means of Currents of High Frequency.

From the cuts presented herewith the reader will be able to obtain an understanding of a lighting system devised at incandescence. To express the idea in Mr. Tesla's own words: "Any body capable of conducting the high tension current described, and properly inclosed in a rarefied or exhausted receiver, may be rendered luminous or incandescent, either when connected directly with one terminal of the secondary source of energy or placed in the vicinity of such terminals so as to be acted upon inductively."

These effects referred to, which are generally attributed to "molecular bombardment," "condenser action," etc., Mr. Tesla claims to be able to utilize in the following manner:

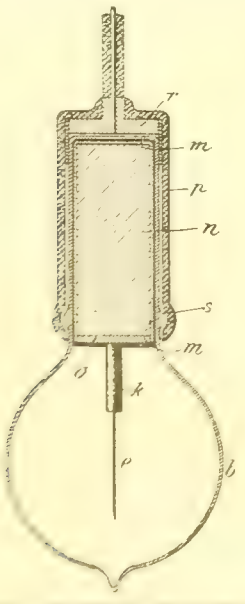
In order that the reader may have a clear idea of the system, it should be explained that the required current of high frequency can be produced by a specially constructed dynamo run in connection with an induction coil. In order, however, to overcome the mechanical difficulties which in such cases become practically insurmountable before the best results are reached, the principle of the disruptive discharge may be resorted to. By means of this latter plan a greater rate of change in the current can be secured. The current for the system illustrated herewith is, therefore, obtained by the oscillatory discharge from a condenser arranged as shown in Fig. 1. In this diagram *G* is the primary source of current, which, it may be assumed, is an alternating current generator of comparatively low

INSTRUMENT FOR MEASURING THE STRENGTH OF MAGNETIC FIELDS.

electromotive force. Under such circumstances the potential of the current is raised by means of an induction coil having a primary *P* and a secondary *S*. By the current developed in this secondary, a condenser *C* is charged and this condenser is discharged into a circuit *A*, having an air gap *a*, or, in other words, a means for maintaining a disruptive discharge. By this method a current of enormous frequency is produced. The next step is to convert this arrangement into a working circuit of very high potential. To do this there is connected up in the circuit *A* the primary P^1 of an induction coil having a long fine wire secondary S^1. The current in the primary P^1 develops in the secondary S^1 a current or electrical effect of corresponding frequency, but of enormous difference of potential, and the secondary thus becomes the source of the energy to be applied to the purpose of producing light.

The light giving devices may be connected to either terminal of the secondary S^1. If desired, one terminal may be connected to a conducting wall *W* of a room and the other arranged for connection with the lamps. In such case the walls are to be coated with some metallic or conducting substance in order that they may have sufficient conductivity.

The light-giving devices may be ordinary incandescent lamps; it is preferred, however, to use specially designed lamps, such for instance as are illustrated in Fig. 2. This lamp consists of an exhausted globe *b* formed with a cylindrical neck, within which there is a tube *m* of conducting material on the side and over the end of a plug *p* of insulating material. The lower edges of this tube are in electrical contact with a metallic plate *o*, secured to the plug *p* and all the exposed surfaces of the [illegible] are carefully coated and [illegible] The light-giving body *r*, in this [illegible] is electrically connected [illegible] of the globe fits into a socket [illegible] with a more or less complete metallic lining *s*, electrically connected by [illegible] to one pole from the generator. The metallic lining *s*, and [illegible] condenser.



Another form of lamp is illustrated in Fig. 3. In this cut *b* is a rarefied or exhausted glass globe in which there is a conductor *e*. To this electrode is connected a metallic conductor *f*, which passes through and is sealed in the glass wall of the globe. Outside of the globe, it is united to a copper wire *g*, by means of which it is electrically connected to one pole or terminal of the source of current. Outside of the bulb, the conducting wires are protected by a coating of insulation *h*. Inside the globe, the supporting wire is inclosed in and insulated by a tube *k* of a refractory insulating substance, such as pipe-clay or the like. A reflecting plate *l* is shown applied to the outside of the globe. This form of lamp is a type of those designed for

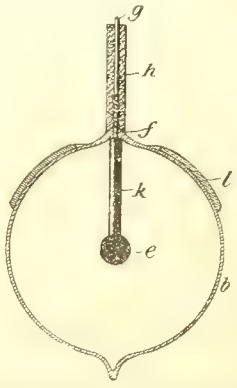


FIG. 3. TESLA'S METHOD OF PRODUCING LIGHT BY MEANS OF CURRENTS OF HIGH FREQUENCY.

direct electrical connection with one terminal of the source of current; but it is asserted that there need not be a direct connection, for the carbon or other illuminating body may be rendered luminous by the inductive action of the current. It may be mentioned that it is considered as necessary, by Mr. Tesla, that care be taken to reduce to a minimum the opportunity for the dissipation of the energy from the conductors intermediate to the source of current and the light-giving body. For this purpose the conductors should be free from projections and points and well covered with a good insulator.

Instrument for Measuring the Strength of Magnetic Fields.

According to a correspondent at the Frankfort Exhibition, the display of Hartmann & Braun is devoted largely to its electrical measuring instruments, which are a specialty of this house. There are shown numerous and important novelties, among which is an instrument for measuring the intensity of a magnetic field. The principle of this device which is illustrated in the cut, rests on the alteration in resistance that a wire of bismuth undergoes when placed in a magnetic field. A thin insulated wire of this metal is wound bifilarly into a spiral, the ends being connected with the terminal screws of a vulcanite handle. The thickness

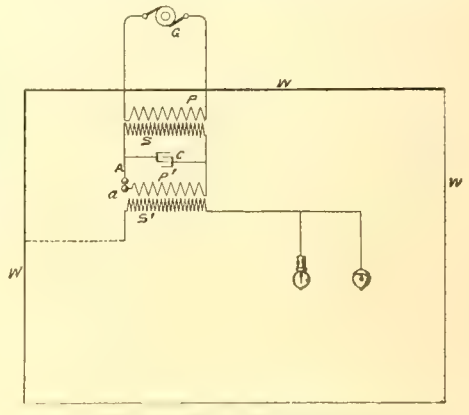

FIG. 1. TESLA'S METHOD OF PRODUCING LIGHT BY MEANS OF CURRENTS OF HIGH FREQUENCY.

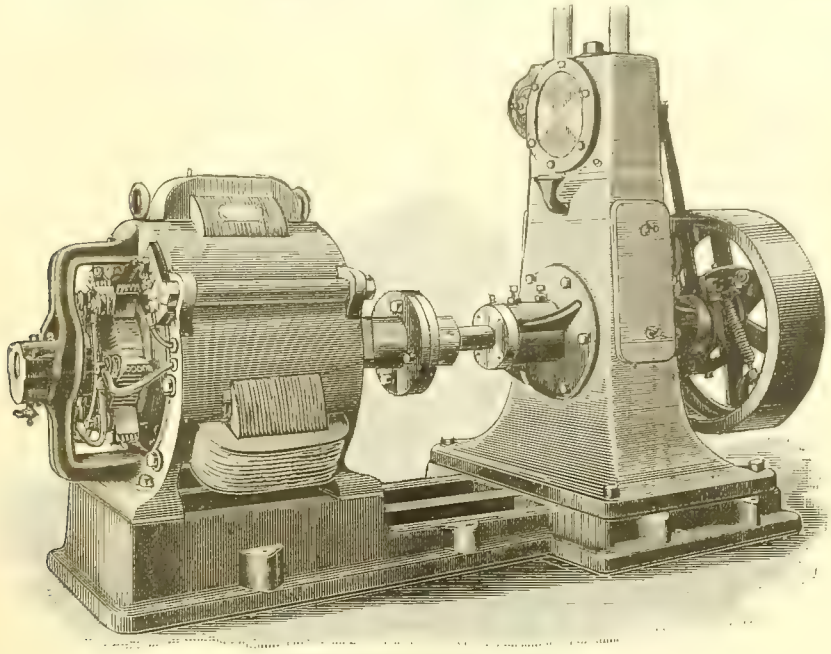
of the spiral is only about .04 inch, so that it can be inserted in very narrow spaces, as, for instance, the air-gaps of dynamos. The variation in the resistance is a measure of B, and 1000 lines per square centimeter correspond to a [illegible] per cent. variation, a more exact correspondence is to be seen from the gauge curve of the instrument.

About the first appearance of the Prince of Wales since the baccarat scandal in his character as a patron of science was at the celebration in honor of the centennary of Faraday's birthday on June 17th. That the spell of his influence has been but little abated, however, is shown by the fact that all the newspapers reported the prince's remarks verbatim and nearly all summarized in a few lines the really remarkable oration delivered by Lord Rayleigh in honor of the great electrician.

Perret Dynamo on the "Romola."

The accompanying cut shows the plant recently installed by the Elektron Manufacturing company of Brooklyn, N. Y., on the steam yacht "Romola" belonging to Joseph Pulitzer, proprietor of the New York *World*. The dynamo is an 85 light slow speed Perret machine of the usual construction, waterproof and connected by a flange coupling to the shaft of the steam engine, running 585 revolutions per minute. The combination is placed on a substantial bracket in the side of the engine room, and runs without any appreciable vibration.



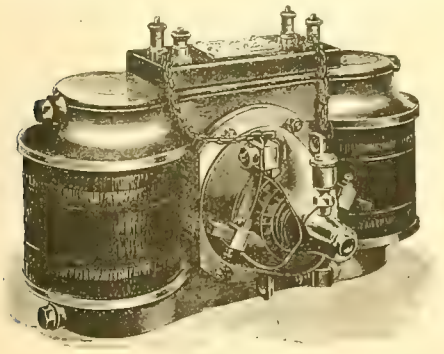
PERRET DYNAMO ON THE "ROMOLA."

The yacht, which is 170 feet long, is well lighted in the evening by the dynamo direct and by storage batteries during the day, or when the dynamo is not running.

Where it is desirable to be very economical in floor space a different style of coupling is used by the Elektron Manufacturing company, and the space between engine and dynamo may be shortened up considerably.

Prentice Dynamo.

The dynamo represented in the accompanying cuts is the invention of Napier Prentice, an English electrical engineer. It is claimed to have an efficiency of 90 per cent. The armature core is made up of disks of soft charcoal iron. It is claimed that the system of winding is peculiarly effective—so much so, in fact, that a high electrical efficiency can be obtained at the comparatively slow speed of 500 revolutions per minute. The armature is protected from injury by metal cases at each end, which entirely cover and inclose the wires and commutator connections, and by strips of fiber or bone placed over the wires and filling up the spaces between the iron projections on the circumference. The field magnet coils are protected by zinc cases, which are securely soldered to the metal flanges at each end of the coil. The commutator is built upon an iron sleeve so that it can be readily replaced by a new one if necessary. The dynamos are very light. One giving an output of 150 amperes at 100 volts only weighs about half a ton and runs at the low speed of 800 revolutions per minute. The illustrations were reproduced from *Electricity*, London.



PRENTICE DYNAMO.

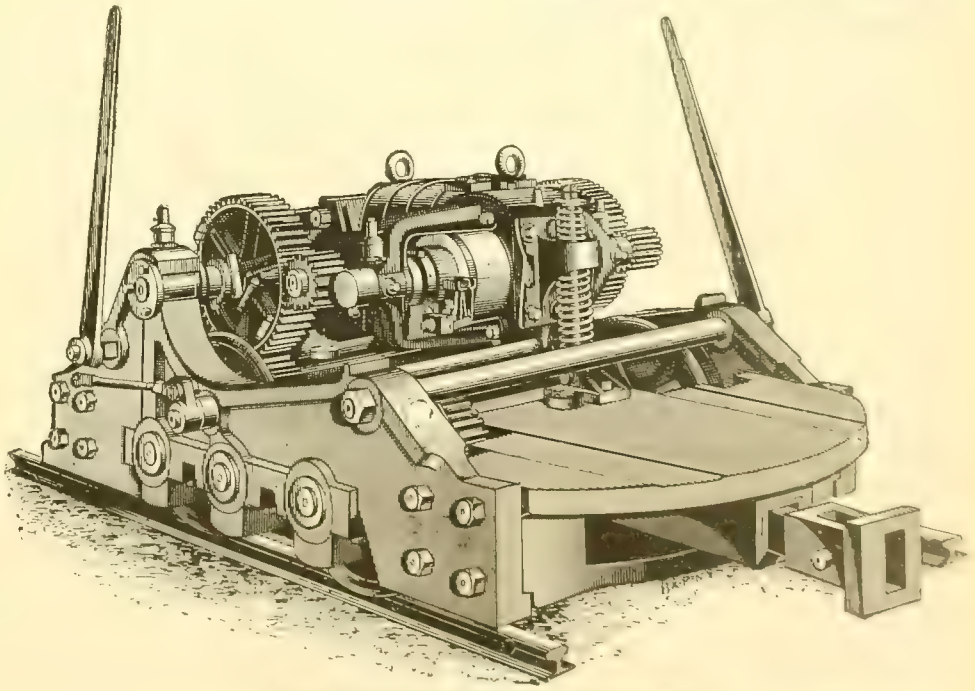
Cedartown, Ga., has voted to bond itself to the extent of $50,000 to erect an electric light plant and water works.

Edison Electric Locomotive for Mines and Mills.

In the accompanying cut is shown a new form of electric locomotive for mill and mine work placed on the market by the Edison General Electric company.

The motor is protected by a metal housing arranged to give ready access to the commutator and brushes. By simply lifting a slide and removing four bolts and raising the main cover, the whole motor is exposed to view, as shown in the cut.

By this arrangement the motor is protected and at the same time access to the working parts may be gained. A 15 horse power motor is used, one end of which is hung to a support on the frame, and the other flexibly suspended after the street railway practice. The motor is connected to both axles by direct gearing. There is a seat at either end for the engineer, within easy reach of the lever of a hand brake, and a switch of the street railway type, the latter having one lever by which the motor is brought to a standstill, started up or reversed, and the speed regulated according to requirements.



EDISON ELECTRIC LOCOMOTIVE FOR MINES AND MILLS.

In the construction of this locomotive care has been taken to distribute the weight so that all four wheels will bear evenly, to insure a maximum traction as both axles are driven from the same motor.

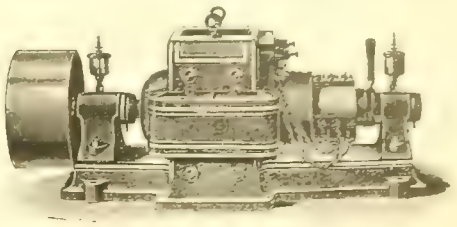
Trouble has been engendered between the Pittsfield, Mass., Electric company and the city authorities and citizens generally. It is charged that the company set its poles wherever it wished, cutting down trees and disregarding the wishes of the people.

Reorganization of the Westinghouse Company.

The reorganization of the Manufacturing company is completed and the directors met on [illegible] to settle all the details connected with the project.

The stockholders of the company held another meeting last week Tuesday, but an adjournment was once more decided upon. Mr. [illegible] company, being absent, Mr. [illegible] acted as chairman and announced that almost three-fourths of the stock of the company had already been sent to the Mercantile Trust company, the stockholders assenting to the proposed plan of reorganizing the company; that the plan had met with general approval everywhere, and that at the next meeting the reorganization of the company would take place. He also announced that Mr. Westinghouse and others, whose presence was necessary at the final meeting, were now in the East. Mr. Bannister suggested that the meeting adjourn until July 15th, which was done after the report had been accepted.

The work of reorganizing the Westinghouse Electric & Manufacturing company has now been in progress for over six months and during that time, in spite of hampered facilities, the management has been able to continue the business. The shops have not been idle a single day. This year the number of workmen was greatly reduced, yet, it is claimed, the capacity has been more than doubled, and to-day about seven hundred workmen are employed in the several departments. One or more electric street railway companies have their cars equipped with the Westinghouse system in the following named cities: Des Moines, Ia.; Lansing, Mich.; Champaign, Ill., Salt Lake City, Utah; Springfield, Mo.; Merrill, Wis; Moline, Ill.; Lincoln, Neb.; Pittsburg, Kan.; Cleveland, O.; Greensburg, Pa., Glen Echo, D. C.; Dayton, O., Richmond, Va [illegible] Lebanon, Mo., Reading, Pa., Terre Haute [illegible] lay, O.; Dallas, Tex., Maysville, Ky., Sandusky, O.; Seattle, Wash.; Helena, Montana; Waco, Tex.; Portland, Ore; Burlington, Ia.; Flushing, L. I.; Louisville, Ky.; Nashville, Tenn., [illegible] Pa., Washington, Pa., Austin, Tex., [illegible] den, Utah; Pittsfield, Mass.; Ottawa, Ont.; Baltimore, Md.; Glens Falls, N. Y., [illegible]



PRENTICE DYNAMO.

The Westinghouse roads in these cities are in actual operation, and in many cases orders have been received for an increase of the equipment. The other departments of the

works have been equally diligent in meeting the demands of the central station incandescent as well as arc lighting. A fan motor which can be attached to incandescent circuits has been placed on the market. It has proved very successful. Much of the success of the plans of the Westinghouse company under these difficulties has been due to the excellent judgment of the present manager.

Thomson-Houston Electric Tramway for Mills.

In the accompanying illustration is shown an electric tramway recently installed by the Thomson-Houston Motor company of Boston at the works of the Pittsburg Plate Glass company, Ford City, Pa. This installation is especially interesting owing to the peculiar conditions under which it is working. The tramway is used to transfer the immense plates of glass in process of manufacture from one part of the works to another.

Four locomotives, one of which is shown in the accompanying illustration, are in use, each being equipped with a twenty horse power Thomson-Houston motor. This machine is used not only to propel the locomotive, but also to drive a hoisting drum, which, by means of special gearing, is thrown in or out at will.

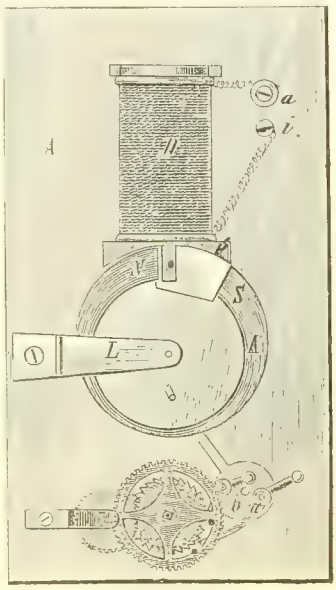
Glass is loaded on cars which run on tracks at right angles to the main track, and the hoisting apparatus mentioned is used to pull these cars up to the tow-cars, which run on the main track and are hauled by the locomotives. The tow-cars are ordinary platform trucks. The grade on the main track is such that the platforms of the trucks are on a level with the side track, and the cars when loaded are placed on the trucks and then transferred to any desired point.

There are two lines of main track, both of which are entirely inside the works and each of which is about 700 feet in length. The gauge of the road is nine feet and ten inches, which is probably the broadest gauge ever used in tramway work. The overhead single wire construction is used and the current for the operation of the motor car is secured from a 500 volt Thomson-Houston generator.

Protection against Lightning.

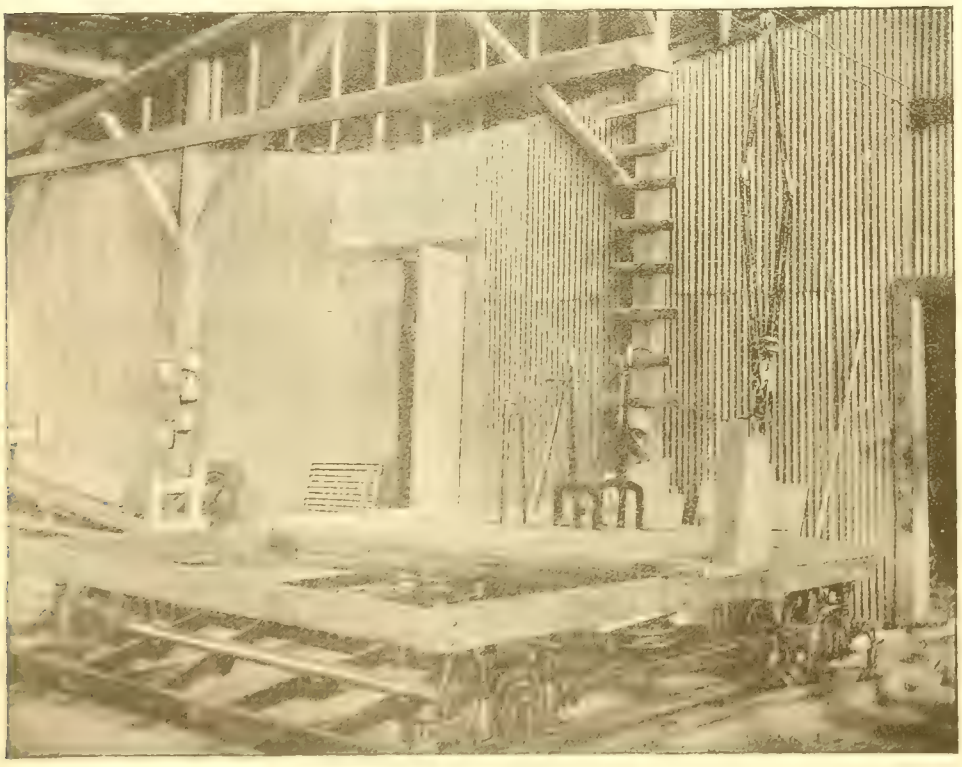
Prof. Henry A. Rowland of the Johns Hopkins University is reported as follows in the Baltimore *Sun* in an interview on the subject of protecting buildings against lightning.

"Recent scientific study has swept away some of the old Hopkins University is protected from lightning by the roof and spouting. You can safely class all patented lightning rods as being of little value beyond conducting rods that any man can put up himself, because the simple principle underlying all is that the lightning will follow the best conductor. The idea so largely adopted in the erection of lightning rods, that a small band of glass will prevent the electric current from passing to a better adjacent conductor, seems playful. While it is true that lightning is attracted to an elevated point or angle, when you cast your eyes over a city like Baltimore and see the large number of such points and angles, the use of pointed rods fades into insignificance as compared with the method of roofing with a good conductor. This was well illustrated by the incident of lightning striking the great monument in Washington several years ago. The monument is capped with a piece of aluminum, which has metallic connection with the ground by means of the iron work of the interior, but the lightning did not strike the top of the cap. It descended to some



ELECTRIC CLOCK.

copper fixed in the side of the pyramidal top, some distance from the apex, burst a portion of the stone, and, running along the copper into the interior, leaped without any metallic connection to the iron framework and passed to the ground. A framework of copper rods covering the angles and crossing the sides of the immense cap was recommended by me at that time for the future protection of the



[illegible] erected. The ground [illegible] the interior iron work spoken [illegible] to the method is that of the Peabody [illegible] connected with the [illegible] on a stone foundation which [illegible] of lightning, has been connected [illegible] conductor, and no danger [illegible] of a building to strike [illegible] center of a roof and while it

runs along the surface of a body, the body may be broken or crushed by the enormous pressure brought to bear upon it, in the same manner that an explosion of dynamite or nitro-glycerine would cause a fracture. I have some fragments of a church spire struck by lightning which are bound together in their former relative positions, but exhibiting all the fractures produced by the concussion. There is a vast difference between the quantity of electricity and what is known as electrical pressure. This is illustrated in a simple manner by the compression of air. A small quantity of air can be compressed to the same degree to obtain as great an expansive force as a large quantity. The quantity of electricity in a stroke of lightning is not nearly as much as passes along almost any electric wire on the street, but the voltage or electrical pressure of the street wire is rarely 3,000. A volt is the basis on which the pressure is estimated. The voltage of the lightning stroke is roughly estimated at 6 000,000,000 volts. In addition to this appalling difference it may be said that the current of the wire is constant and continuing, while the lightning dart is delivered in the one two-hundredth part of a second. Such an astounding force is capable of doing many strange things."

In speaking of places of safety during an electrical storm Dr. Rowland said that probably as safe a place as any other would be an iron bedstead, provided the ground connection is perfect, this being in line with the above theory, that the lightning would follow the best conductor.

Electric Clock.

The accompanying illustration shows a new design of electric clock in which an alternating current through a single magnet works the escapement.

On a base plate *A* is fastened an electro-magnet *D*, the windings of which are connected to the two binding posts. On the lower end of the magnet core there is a pole piece, or shoe, *P*, which is mounted as shown on a stopper in the center. For the armature there is employed a steel magnet *K*, bent into the shape of a ring and fastened to a brass disk, which is centrally pivoted on a bracket *L*. The motion of this balanced armature is such that the two poles, *N* and *S*, alternately strike against the stopper on the pole shoe of the magnet, as the polarity of the electro-magnet changes with the current. This oscillating disk armature is geared to the escapement of the clock movement in such a way that each swing of the armature moves the escapement wheel one tooth.

These clocks are operated in the same way as other electric time systems. A regulator at the station operates a pole changing device and the clocks are joined in series. Clocks operated on short circuits, with magnets of 3.6 ohms resistance require .08 ampere of current and those for long distance service with magnet of 10.8 ohms resistance take only .04 of an ampere.

This clock, which is manufactured by Georg Kesel, of Kempten, Bavaria, is in operation in Munich, and is said to have given good satisfaction, as shown by the recommendations of the Polytechnic Society of Munich.

The illustrations are reproduced from the *Elektrotechnischer Anzeiger*.

Electric Organs.[1]

By James Swinburne.

The idea, and to some extent the application, of electricity to the mechanism of organs is not new. Gauntlett proposed to build models of various celebrated organs at the London exhibition of 1851, and to connect them all to one console. Barker, the inventor of the pneumatic pallet, worked out what was probably the earliest practical system of electrically controlled organs.

An organ consists essentially of three or four independent instruments. Each instrument is composed of sets of pipes, called stops, arranged in rows, say, crosswise, on what is known as the "soundboard," probably because it is not a soundboard. The pipes are also arranged in rows from back to front, each row corresponding to a key on the keyboard belonging to that organ. Each key commands a valve, or pallet, letting wind into a channel under all the front to back row belonging to it. Each stop has a long perforated slip or slider running under it, which can be moved so that the holes correspond or not with those leading to the pipes. These sliders are controlled by the draw-stops. A fourfold organ has one pedal and three manual keyboards, called "great," "swell" and "choir." Further mechanism is necessary to connect various keyboards, and to admit of rapid changes of the arrangement of the draw-stops. This appears very simple, but when an organ has about forty stops and over fifty draw-stops it becomes very complicated. The first trouble is that it soon becomes almost impossible for the fingers of the left hand to work air valves or pallets large enough to control the wind for twenty or thirty large pipes, even if equilibrium valves are used. I am, as far as possible, using engineering, and not organ building, nomenclature. To get over this, the air relay, or pneumatic pallet, has been adopted in large organs. The finger then controls a tiny equilibrium valve, which controls an air bellows that does all the work. When this system is applied to the great organ of a small instrument, it is generally arranged to work the "choir" and "swell," too, when coupled to the "great."

There is still another difficulty. In large instruments

[1] London *Electrician*.

the pneumatic pallets frequently have to be a long way from the player, and the connections are apt to alter in length and get out of adjustment. In All Saints' Church, Manchester, there is, or was, an organ played from near the reading desk, placed high up on each side of the chancel 70 feet off. It has mechanical connections, but they are not heavy, and seem to work very well. Generally, an arrangement like that used in pneumatic bells is used, and known as the tubular pneumatic system. Barker, however, controlled his little air relay valves electrically, and realized the advantages of electrical connections in admitting of great simplicity in coupling and key mechanism, as well as ease in connecting distant organs. The electric action, as it is called, has developed especially abroad. Messrs. Bryceson have done a great deal, and many English organs have electric connection. In France there are a large number of these combined electric and air relay mechanisms. M. Carre describes several in a valuable article in *La Lumiere Electrique*. Roosevelt, in America has not only developed pneumatic actions thoroughly, but has employed electricity too. The three manual organ at Trinity Church, Boston, has not only pneumatic action for the keys, but a pneumatic stop action which admits of an exceedingly convenient composition pedal arrangement. The pedal on being pressed and hitched down draws its corresponding set of stops, and shuts them off again when allowed to rise, without interfering with any arrangement that has already been made. There is also an electric solo organ, but it was out of order when I tried the instrument. There is a concert organ by the same maker in Boston with a set of composition pedals, each with a complete set of draw-stops, which can be arranged beforehand, and come into use when the pedal is pressed. I believe the new Riga organ is electrical.

Mr. Hope-Jones has recently paid great attention to the subject of electric actions. Being an electrical engineer and an organist, he is well fitted for tackling such a difficult subject. The console of the organ of St. John's Church, Birkenhead, where Mr. Hope-Jones is organist, is worthy of consideration. Instead of draw-stops at the side of the player there are rows of little tumblers just under the music. A touch at the top or bottom puts the stop in or out. This organ, if arranged in the ordinary way, would have about forty draw-stops. By the use of electric gear, Mr. Hope-Jones produces an organ which has the same effect as an instrument of fifty-three, with the ease of manipulation of one of twenty draw-stops. In addition, it has a whole host of composition buttons, crescendo arrangements and other accessories.

So far electricity seems to have been used to work an air relay only. The use of electricity may easily have been carried very much farther than this. The difficulty has been the supply of electrical energy, and batteries have been used. Mr. Hope-Jones, who has had experience in telephone work, has probably reduced the energy needed to a minimum. It seems obvious, however, that to use electricity to work an air relay for working a valve needing a pull of a pound or two through half an inch is absurd; and our electrical readers may well study the question, as given, say, twenty watts available, the whole mechanism of the ordinary organ might be swept away, and an infinitely more convenient and less costly instrument devised. It is easy to get the power. In England the blower, who does the whole of the work when air relays are used, works a thing like a pump handle up and down. In France he works two levers with his feet. Sometimes the blower is a water motor or a gas engine. All that is wanted is rotary motion. Even if rotary motion is provided, by means of hand cranks, water motors or gas engines, the feeders are generally on the principle of a smith's bellows. We would suggest that such a machine as the Baker positive blower would be very much cheaper and better, giving a uniform supply without beating. The electric power can then be supplied by a very small magneto machine. This need have no commutator; it may supply alternating currents of low enough frequency to be silent. There is then nothing to get out of order, and owing to hysteresis, if closed circuit electro magnets be used, there is practically no sparking at the various contacts. Organ music is limited entirely by the mechanism of the organ, and develops with it. In Germany they have only one sort of organ music, of which the works of Merkel, Rheinberger and perhaps Mendelssohn may be taken as examples. This needs no accessory mechanism, and even modern German organs have, we believe, little as a rule. The well-known organ at Tyne Dock, by Schultze, has no composition pedals, and, if I remember aright, no couplers. In France the organ intersperses showy scraps during church service; and many of the organs are not designed for solid playing. The large organ at St. Eustache, for instance, has the pedals so arranged that the player cannot reach them without sliding along the seat. They have all sorts of arrangements for meretricious effects—tremulants, fancy reeds, and "effets d'orage." In England and the United States organ playing has got as far as it can without a change in organ construction. The average church organ spends its time in the monotonous accompaniment of hymns and chants, but the concert instrument plays German fugue music, German chorale organ music or the resulting German organ sonata; then it plays Guilmant and light French music; and then it indulges in a development which is essentially English, the organ arrangement. As much of an orchestral movement as can possibly be compressed into the region of ten fingers and two feet is crammed on three staves, and the organist has to change his stops as best he can. It is probably only in England and America that such things as the overtures to "Der Freischuetz" or "A Midsummer Night's Dream" are played on organs. It is only because the mechanism does not give the right combinations quickly enough, if at all, that the overture to "Tannhauser" does not figure on recital programmes.

It is difficult to think of all that can be done easily and cheaply by direct electric mechanism. If each key makes circuit with a set of small electric valves one to each pipe, and if the returns to each stop are controlled by what corresponds to the draw-stop, all the ordinary mechanism of pneumatic pallets, expensive soundboards—which sometimes warp—trackers, sliders, rollers, etc., may be swept off. It may be remarked parenthetically that the abolition of pneumatic pallets is itself most desirable. Apart from expense, they tend to develop a bad style of playing. The organist cannot accent a note by playing it louder, so emphasis is given to it by clipping the note before it a little short. Phrasing thus depends on perfect instantaneousness of the action, which is not always found with the air relay. In a cathedral organ music gets mixed up into a sort of roar, which rolls down the aisles in a way poets like, and slovenly phrasing does not matter; but in a concert room an organist accustomed to a large instrument generally bears evidences of it. With electric mechanism, any stop may be drawn on any manual, or pre-arranged for any manual and composition button. Any grouping may thus be adopted. In orchestral music, though there are about twenty staves in the score, the instruments fall roughly into a few groups. It should be easy to group the corresponding stops on the organ in the same way for playing orchestral music. This can be done by electricity. Again, in playing from the ordinary piano score of oratorios, there are four lines of voice parts, which demand one keyboard, and two lines of condensed accompaniment, which demand one or two keyboards, which must be coupled instantly to the voice keyboard when there are no hands available to play them. Existing organs generally meet these last requirements. Electric action admits of still another development. In a medium sized hall, one manual may be an ordinary grand piano. A piano could not be combined with an ordinary organ, because the touch is different; but if the console is detached from the organ so as to give breathing room for the piano, the addition of the contacts to the keys will not interfere with the touch of the piano at all. This suggestion will strike many as odd, some may say barbarous, but the harp may almost be considered part of the modern orchestra, and apart from concertos, the piano might also be absorbed too, especially if it were more portable, and several could be employed together.

Enough has been said to show the enormous advantages of simple organ mechanism. One great difficulty will probably be in organ builders themselves. They are often too apt to regard electric action as complicated, untrustworthy and expensive. It must be remembered that electric work has advanced enormously within the last few years; and if electricity can sweep away the whole of the rest of the action mechanism from organs, it is certainly worth consideration. The excellence of the organ at Birkenhead points to the advisability of organ builders going to electricians to get the electrical part of their actions put right, instead of designing it themselves, and then rejecting it as costly or untrustworthy.

CORRESPONDENCE.

New York Notes.

NEW YORK, June 27.—"Four more persons, all women, suffocated by gas from an open burner. Three accidents in one, with a suicide added. How long before the ever ingenious but sometimes dilatory Yankee inventor shall come to our rescue by adding a tell-tale or self-snuffer, so to speak, to every gas burner?" This mournful plaint was uttered by one of the great metropolitan dailies at the head of its editorial columns this week. That such a shocking occurrence should have called forth even so much comment from the daily press is passing strange, because we are all accustomed to the deadly work of illuminating gas. Scarcely a week passes but one or more lives are thus silently snuffed out and nobody takes any notice, but four in one night is an unusual record. Imagine the columns of sensational matter that would have deluged our breakfast tables had the dynamos instead of the gas holder been to blame for this wholesale slaughter. The newsmongers of New York would have been satisfied with nothing less than the immediate electrocution of all the officers of the company, from the president down to the man in charge of the station. Yet nobody proposes to indict a gas director or superintendent, and Mayor Grant never even hints that he would like to pull up all the gas mains in New York until the burners are robbed of their murderous powers.

Those who talk so glibly of the "dangers of electricity" would probably be surprised to learn that there are twenty deaths in New York from gas to one caused by electricity. In New York there were more than 1,300 accidental deaths last year, of which just two were ascribed to electricity, while over forty were put down to illuminating gas. But suffocation by gas is a trite occurrence and can no longer be written up "artistically," while there is something novel and mysterious and sensational about electricity, so for a long time to come we shall continue to read of the 'dangers of electricity," and gas will go on insidiously committing weekly murders without provoking comment or protest.

The rapid transit question continues to crop up at various times and in various lights. The elevated railway people, balked in their endeavor to annex the best part of Broadway and the whole of the boulevard, throw cold water on the electric underground scheme whenever [illegible]

[illegible] electrical engineers will not be able to construct motors of [illegible] opment of electrical engineering, although at the same time it must be acknowledged that his opportunities of [illegible] very little attention to electrical engineering, and in fact manages to get along without it. Be that as it may, Mr. Gould disclaims all pretension to any such knowledge, stating that to him electricity is an "unfathomable subject" which he leaves entirely to experts. In that case it seems rather gratuitous on the part of Mr. Gould to venture on an opinion as to what "experts" can or cannot do, and just as valuable an opinion might have been obtained from one of Mr. Gould's messenger boys. The *Sun* supports Jay Gould, and Mr. Dana doubts whether a motor can be built to do the work. Mr. Sprague has challenged Mr. Dana to back his opinions to the tune of $50,000, but Mr. Dana preserves a discreet silence. Last year the venerable editor of the *Sun* spent his vacation in Spain, and he appears to have acquired some of that country's conservatism and opposition to progress; this year he would do well to make a tour of this country and see what electric motors are doing in many large towns. He will then think better of the motor than he appears to at present.

The engineers of the Rapid Transit commission have lately been engaged in sinking shafts along Broadway to discover at what depth bed-rock was to be found. The result of this work has been highly satisfactory, rock having been found at an average depth of about 100 feet for a considerable distance, the minimum being 78.8 feet at Dey street, and the maximum 163.5 feet at Duane street. It was prophesied that trouble would be met with at Canal street, where Broadway runs into a hollow. It was said that a subterranean creek existed here, containing nothing but soft mud, which would render tunneling practically impossible. The prophets were all wrong, however, as rock was struck at Canal street at a depth of 87.6 feet, the ground above consisting entirely of strata of coarse gravel and sand. The Rapid Transit commissioners are very much pleased with the results of the work, and they consider that it has been conclusively demonstrated that not only are many of the threatened difficulties absolutely nonexistent, but also that the lower section of the road can be constructed much more easily and cheaply than had at first been supposed. It is estimated that the tunneling through the sand and gravel that has been met with so far can be advanced at the rate of fifteen or twenty feet a day. The commission is now engaged in considering an East Side line.

The motive power in the tunnel which is being built under the North river by the Hudson Tunnel railway company, connecting New York city with Hoboken, will be electricity, which is conceded to be the most practical and economical. The electric locomotives used will be much after the style of those used in the London underground railways. The Thomson-Houston Electric company has taken the contract, it is claimed.

The Metropolitan Telephone company inaugurated this week the third of its model telephone buildings. The new exchange is at Spring street, and serves what is known as the dry goods district. It is equipped with a multiple switch-board of the latest type, embodying all the improvements known to telephonists. Not an overhead wire enters the new building, all the subscribers being connected through underground cables, and the change from the old office to the new was effected in a novel and effective manner entirely by means of underground cables. The old exchange was operated by the Chinese system and [illegible] its abandonment this system disappears from the telephone service of New York. The Metropolitan company has for some years past been doing very progressive work in reorganizing its general plant and equipment, and all the new exchanges are in buildings specially erected for the purpose. The amount of underground telephone cable lying beneath the streets of New York is now something prodigious, and is daily being added to. [illegible] time a circuit could be run the entire length of Manhattan Island from the Harlem River to the Battery exclusively through underground cables, without an inch of overhead wire and Steel Mayor Grant is now [illegible] he finds so few poles used for electrical work in the streets now that he is casting longing glances at the barbers' poles [illegible]

The subway deadlock will probably find a solution before very long. The electric light companies who have [illegible]

very first, owe the subway company large amounts for rental of ducts. No payments have been made on the ground that the rentals were excessive, and when the subway company threatened to cut the cables if a settlement of their little bills were not made, the electric light companies applied for an injunction to prevent the execution of such violent methods, which to them savored "of the earth, earthy." A temporary injunction was granted, but on a further hearing Judge Ingraham denied the motion, and refused to continue the injunction. The Supreme Court, General Term, has just affirmed the decision of Judge Ingraham, the opinion of the court being written by Presiding Justice Van Brunt and Justices Barrett and Patterson. This decision is, in vulgar parlance, a "facer" for the electric light companies, who will now have to pay up or submit to having their cables cut It is scarcely probable that they will be willing to incur the losses that would result from a general interruption of the lighting service, and presumably they will now at least pay something on account to the long suffering Subway company, which certainly must need the money bad enough.

The First Battalion of the Naval Militia of the state of New York was legally enrolled a few nights ago by Adjutant General Porter, and New York now presents a naval force of 201 men. Many electrical men are members of the battalion, and great interest has been taken in it among electrical circles in New York, especially since the publication of Lieut. Bradley Fiske's very able paper on "Electricity in Modern Warfare," read before the New York Electrical society last fall. The commanding officer of the battalion is Lieut. Commander Jacob W. Miller. The battery commanders are: First Battery, Lieut. S. Dana Greene; Second, W. Butler Duncan; Third, Louis Mowbray; Fourth, T. M. Forshen. The battalion will go on a cruise with the squadron of evolution on July 27th, when the men will be drilled in handling heavy guns and rapid firing guns, target practice, boat tactics and landing as a naval brigade to assist land forces.

News comes from Washington of an important omission in the specifications for cruiser No. 13. It appears that no provision has been made for that very necessary part of the equipment of a modern man-of-war, namely, the electric lighting plant. Nobody seems able to explain how the omission came about. The responsibility rests between the Equipment Bureau, which has charge of such matters as electrical appliances, and the office of the Judge Advocate General which superintends the preparation of the specifications. It appears that all the bids received for the construction of the vessel are so close to the appropriation that not enough money will remain to provide an electric light plant under a separate contract. The lowest bid leaves a margin of only $60,000, whereas the electric light plant would, it is estimated, cost $100,000. The secretary tried to get the contractors, who have sent in bids, to throw the electric plant in, but none would agree to do that. It is probable that the lowest bid, that of the Bath Iron Works, will be accepted, and the cost of the electric light installation limited to $60,000. W. L. H.

San Francisco, Cal.

SAN FRANCISCO, Cal., June 26.—Dr. Thomas Addison, district manager for the Thomson-Houston Electric company, was closed a contract for the equipment of the San Francisco & San Mateo Electric road with Thomson-Houston apparatus. The initial plant will consist of six 80 kilowatt generators and 30 cars, 15 of which are to be 16 foot, single track cars, each carrying two 15 horse power motors, and the remaining 15 cars are to be of the latest 32-foot, double track pattern, each truck carrying a 25 horse power motor. It is hoped that the first division of the road will be completed in October next.

The closing of this contract means that the Thomson-Houston company will equip what is to be perhaps the nearest approach to an electric trunk line of any road in [illegible] San Mateo company has [illegible] for the line from San Francisco, [illegible] town of San Bruno, Millbrae, [illegible] Belmont to Redwood City, a [illegible] Southern Pacific route, [illegible] extension of the [illegible] and through [illegible] to San Jose, a [illegible] from [illegible]. It is evident, [illegible]

[illegible] electrical [illegible] for the [illegible] of [illegible] a [illegible] power

motor and 56 storage cells of the 23 M type, manufactured by the Accumulator company, New York. The normal speed of the craft will be from 6 to 8 miles per hour, and it is capable of spurting at the rate of 12 miles per hour. It will run about 70 miles on one charging, and, in addition to the usual incandescent lamps necessary for its illumination, it is to be provided with an electric search light and an electric fog horn. The accumulators are to be charged by means of a 4 horse power gasoline engine and a 2.5 kilowatt Edison dynamo. The Storage company also reports the sale during the week of a 160 light incandescent plant to the San Jose Fruit Packing company of San Jose, and the closing of the contract for the wiring of the Reid boarding school at Belmont for 150 lights, preparatory to the placing of a storage plant.

The California Electrical society has removed from its former rooms in the Murphy building, and is now quartered in the new Academy of Sciences building. The rooms are nicely fitted up and are lighted by electricity.

The San Francisco *Chronicle* of June 17th contained the following:

"At the close of the executive meeting of the Pacific Underwriters' Association last evening the doors were thrown open, and members of the Insurance Clerks' association were admitted. The object of the meeting was to hear a lecture on 'The Advantages and Possibilities of Electricity,' delivered by George P. Low, electrical inspector of the Pacific Insurance Union.

"The paper was long and very interesting, and is to be supplemented by another one on the 'Dangers of Electric Wires,' to which last evening's lecture was introductory. Mr. Low stated the importance of a knowledge of electricity to the underwriter, and in an easy, entertaining manner pointed out what is known in the abstract of the subtle force of electricity. He compared it to gravity, and suggested that the five senses may owe their action to electricity. Magnetism and electricity were compared and their interconvertible nature was touched upon.

"Taking up the more practical side of the subject, Mr. Low explained the fundamental principles of the dynamo, and figured out that electrical industries of the value of one-quarter of a billion dollars have been built up in the United States through it. The comparative efficiency of the steam engine and the motor, to the great advantage of the latter, was mentioned, and the prophecy was made that all our railroad lines will one day be operated by electricity. What has been done was summed up neatly, and then the possibilities of electricity were referred to, closing a most entertaining paper."

The Pacific Postal Telegraph company has completed the changing of the terminus of its cable between San Francisco and Goat Island to the end of the Clay street wharf. At the same time a new cable was laid and in about ten days a similar cable will be laid from Goat Island to Seventh street, Oakland. The cost of the cable just laid was over $25,000. It consists of ten separate conductors, covered by an armor of 18 No. 2 galvanized iron wires. The cable proper was made in England, but the armoring was done by the Roeblings.

S.

Detroit, Mich.

DETROIT, Mich., June 30.—The Supreme Court of the State of Michigan has affirmed the decision of Circuit Judge Reilly in the suit of the Detroit City Railway vs. M. B. Mills and others, property owners on Mack avenue, this city, arising from the construction of an electric street railway on that avenue. The Mack avenue electric line was built by a corporation and sold to the Detroit City Railway company. M. B. Mills, one of the largest property owners on the street, aided in cutting down the poles supporting the electric wires. The company secured a temporary injunction, and the trial of the suit occupied several weeks. The property owners claimed: First that the act under which the complaint was instituted was unconstitutional, second, that the company had no right by its franchise to use electricity as a motive power, third, that the company in the erection of poles trespassed on the private property of the defendants.

The court held that the claim of the unconstitutionality of the act under which the company was organized was not sustained. The second contention, that the city does not possess the power to permit operation of cars by electricity, is disposed of by the answer that it is a matter between the company and the state, and that the defendants are not in a position to raise the issue. The mere usurpation of corporate power does not confer upon the individual the right to bring suit to restrain the unlawful exercise of authority. If the state choose to raise it, or by its silence permit the action, no others can complain so long as the personal or property rights of the individual are not invaded or affected. The court also finds it unnecessary to discuss the proposition that the right of the company was not conferred in the original act, as subsequent mandatory acts conferred such right, which was, however, to be used under authority of the council. The opinion also holds that the use of streets for street railway purposes does not impose new burdens and servitude beyond the power of the city to authorize without additional compensation to adjoining lot owners. The court holds, however, that the tracks cannot be constructed in a street too narrow to admit the passage of cars and other vehicles at the same time. The road bed and track must be built substantially with the level of the street so as to permit vehicles to cross without difficulty, and the poles must be placed so as not to interfere with the right of ingress and egress to abutting property. Justices Morse and Grant dissent from the opinion. This decision of the Supreme Court removes an objection which the Detroit City railway has claimed to be an obstacle to using electricity as a motive power.

The Detroit Electrical Works contemplate putting up one of the most extensive electrical manufacturing establishments in this country. The new works will include a machine shop, foundery, pattern shops, finishing shops, steam forges, erecting shops, carpenter shops, and laboratories, and possibly a large power plant capable of furnishing an electric current for the motors of the whole manufacturing establishment. The present works will be utilized for manufacturing electrical supplies and machinery. The machine shop of the new works will be a large structure, and each department of the work will be entirely separated from the others. The various buildings, while not taking up the whole space of the land, will occupy a large share of it, and they will be so arranged that additions can easily be made. All of the shops will be fitted up with overhead electrical traveling cranes. The intention for the next year's work is to turn out at least five complete steel car electrical equipments per day and one complete generator of a capacity of not less than 100 horse power. The cost of the buildings is estimated at $200,000 to $300,000 including the additional machinery. The plans and specifications are not yet complete, but they are expected to be finished so that work may be commenced in July, and the works ready for operation by January 1st. The purchase of the property was consummated last week. All the machinery will be operated by electricity, and the shifting and hauling of cars about the ground will be done by means of an overhead trolley system. There will also be passenger cars operated by electricity and electric locomotives, thus giving visitors an excellent opportunity to examine the company's system completely. At present the works are now running three hours overtime, beside employing the facilities of the Dry Dock Engine works in turning out the different mechanical parts of new equipment.

Louis Warfield, lately with the Pennsylvania Railroad company, is now general manager and treasurer of the company. The other officers are: President, Hugh McMillan; vice-president, William A. Jackson; secretary, William H. Wells.

The first electric cars to run regularly in Bay City were started June 1st. The cars were greeted with cheers all along the route. The majority of citizens herald this as the beginning of a change over the whole street railway system of Bay City.

President Hugh McMillan and General Manager Warfield of the Detroit Electrical Works have recently returned from an extended trip through the East in the interest of the company. Frank B Rae, electrical engineer of the Detroit Electrical Works, was in Springfield and Decatur, Ill., and Grand Rapids, Mich., last week on a tour of inspection.

The Detroit Electrical Works have changed the shape of the channel bars of their street car truck so that the motor rests direetly over the frame instead of being suspended from it. The cross bar is bent so that it is only necessary to open the trap door in the car floor and take out the armature.

Brownlee & Co. a few days since shipped a carload of cross arms to Pedras Negras, consigned to the Mexican government.

The final details of the purchase of the Brush Electric Light company's plant by the Peninsular Electric Light company have at last been completed, and the new corporation has elected officers. The pecuniary consideration of the sale is a round $600,000, or $25,000 more than the stock of the old Brush company. The new corporation assumes all the Brush company's indebtedness, gives a bond and mortgage back on the plant, and agrees to keep up the plant and business of the old company, making such improvements from time to time as are necessary to hold and increase its business. The assets of the old company comprised real estate, 150 towers, 600 miles of lines and

as complete a plant for incandescent and arc lighting as can be found in the United States. Among other conditions of the sale was a settlement and discontinuance of the law suits pending between the Brush company and the Fort Wayne Electric company. Without going into the details of the litigation over tower and double carbon lamp patents, it may be stated that the Detroit Electric Light and Power company will now be able to use double carbon lamps without further dread of injunctions, but its towers will probably be taken down and the Brush towers used instead. For president the stockholders have selected R. T. McDonald of Fort Wayne, Ind., who is also president of the Fort Wayne Electrical company; J. L. Edson is vice-president, Edward Hathorne of Boston, secretary and treasurer, and H. L. Wilton, formerly of the Brush company, is assistant secretary. Mr. Hathorne has been traveling auditor of the Fort Wayne company and is one of the best expert accountants in the country. G.

Pittsburg, Pa.

PITTSBURG, Pa., June 27.—There are probably few parts of the country where electricity is so rapidly taking the place of mules or horses as the motive power for street railways, as in Western Pennsylvania. Even in the coke regions the people are after the modern form of rapid transit, and in Connelsville the ground is now being broken for an electric road. The line is to extend from that point through New Haven and Leisenring toward Uniontown, and when it is finished it will be over five miles long. The contract for the building of the road and the furnishing of the motors and dynamos has just been let to a Pittsburg company. The first electric road ever built in the coke region was put down at Uniontown last year, and since it has been in operation it has been running very successfully. This new line from Connelsville will eventually connect with the Uniontown road, and a great deal of interest has been awakened among the people of that district in electrical rapid transit.

August Belmont, Chas. Fairchild and Brayton Ives, the reorganization committee of the Westinghouse Electric & Manufacturing company, have issued the following notice to the stockholders of that company: Inasmuch as holders of considerably more than two-thirds of the stock of the Westinghouse Electric & Manufacturing company have assented to the plan of reorganization, the reorganization committee has decided to limit to July 8th, inclusive, the time in which stockholders may deposit their stock with the Mercantile Trust company. Notice is hereby given that after that date stock will only be accepted subject to such additional conditions as the committee may impose.

At the last meeting of the Allegheny councils the management of the Pittsburg, Allegheny & Manchester Traction company asked permission to have the time for the completion of the road extended until November, because it will be impossible to finish the work any sooner. This was granted.

In the Pittsburg councils the ordinance compelling the telephone, telegraph and electric light companies to put their wires underground came up a few days ago. Representatives of the different companies of this city interested in this ordinance were present at the meeting of councils, and the result was a very spirited discussion on the subject. Mr. Campbell of the Postal Telegraph company stated that it was impossible to put all the wires underground for the reason that the telegraph companies had so many district messenger wires running into the offices of the business houses, which, being only transient wires, could not be put underground, and he thought that the ordinance should be modified to meet that case. He admitted that the main cables could be easily placed beneath the surface of the streets, but he held out for poles for the smaller wires. Mr. Metzgar, the general manager of the District Telephone company, asked to have the ordinance amended so that each company would be allowed to have one pole to each square. Several gentlemen present also stated that they could not see the fairness of the councils in demanding the wires of the telephone and telegraph companies to be put underground when the street car companies, whose wires were really more objectionable than any others, were allowed to leave their wires on the streets. The discussion was postponed at last with the promise on the part of the Department of Public Safety to extend the time for putting the wires underground until November, 1892.

The factories of the Pittsburg Plate Glass Works at Ford City, Pa., are to be lighted by electricity. In addition the company has made a contract for the installation of a power plant to run an electric tramway. The tramway is to convey the glass from the polishing tables to the various departments in the factory. This is the first electric tramway used for that purpose in the world.

B. L. W.

PERSONAL.

J. L. Blackwell, general manager of the Baxter Electric Motor company of Baltimore, Md., was in Chicago Monday.

Gerald E. Fish, who recently resigned from the superintendency of the Chicago Arc Light & Power company, has been appointed superintendent of lighting at Little Rock, Ark.

W. D. Allison manager of the main office of the Chicago Telephone company, has severed his connection with the company. Mr. Allison had been with the company twelve years

C. D Crandall has been appointed to succeed Chas. E. Brown, as manager of the Western Electric company, Chicago. Mr. Crandall will enter upon the duties of his new position at once.

NEW INCORPORATIONS.

West Lexington Land company, Lexington, Va.; capital stock, $80,000; light, heat, power, etc., electric works, waterworks.

Plattville Electric Light & Power company, Plattville, Wis.; capital stock, $10,000; supplying electric light and power at Plattville, Wis.

Milwaukee & Wauwatosa Electric company, Milwaukee, Wis.; capital stock $75,000; to operate street railroad between Milwaukee and Wauwatosa.

Columbia Mining & Land company, Columbia, Va.; capital stock, $250,000; electric light, heat, power, etc., mining, gas works, manufacturing.

Canajoharie Electric Light company, Canajoharie, N. Y.; capital stock, $10,000; manufacturing and using electric light for lighting and heating purposes.

Star Light company, Oakland, Cal; capital stock, $2 500,000; to manufacture, produce, sell, distribute and supply electric power and electric light, and other artificial light.

Union Electric company (incorporated in W. Va), New York, N. Y.; capital stock, $2,500; manufacturing, selling, renting and using electrical appliances of all kinds.

Winters Electric company, Chicago, Ill.; capital stock, $10,000; to manufacture, construct, purchase and sell all kinds of electrical and magnetic apparatus and appliances.

Laclede Power company of St. Louis, St. Louis, Mo; capital stock, $75 000; to make and furnish electric power for mechanical and manufacturing purposes, also electric lights.

Inter-state Complete Electric Construction company, St. Louis, Mo; capital stock, $10,000; to construct and operate waterworks, gas and electric plants for furnishing heat and power and light.

Enterprise Construction & Supply company (limited), New Orleans, La.; capital stock, $50,000; buying, selling and manufacturing all kinds of electrical machinery and supplies, engines, boilers, etc.

Waterville & Fairfield Light & Railway company, Waterville, Maine; capital stock, $200,000. To operate the Waterville & Fairfield Railway and electric light companies at Waterville and Fairfield.

Illinois Judson Power company, Chicago, Ill.; capital stock, $1,000,000; to manufacture, own, use, lease and sell machinery and other appliances for making, using, furnishing and selling power for general purposes.

Topeka Water & Electric Power company (incorporated in Colorado) Topeka, Kan. capital stock, $500,000; to utilize water power from the Kansas River in Shawnee county, Kan., for electric purposes, etc.

Pana Modern Electric Light, Power & Street Railway company, Pana, Ill., capital stock, $50,000; to furnish light and power for city, commercial and mining purposes, and for any other use to which electricity may be applied.

Anderson Electric Street Railway company, Anderson, Madison county, Ind; capital stock, $200,000; constructing, owning, maintaining and operating a street railway in the city of Anderson, Ind., and in the vicinity thereof.

Mattoon & Charleston Street Railway company, Mattoon, Ill.; capital stock, $300,000; to construct, operate and maintain a system of dummy, tramway or street railroad to be operated by electricity or other motive power.

Chattanooga Water & Electric company (incorporated in W. Va), Chicago, Ill.; capital stock, $50,000; owning and operating electric light plant, waterworks, hotel property and pleasure resort in and near the city of Chattanooga, Tenn.

Portable Electric Light & Power company (incorporated in W.Va), New York, N. Y.; capital stock, $1,000,000; manufacture and sell electrical accumulators, secondary batteries, primary batteries, electric light plants and everything pertaining to electricity.

ELECTRIC LIGHTING.

El Paso, Tex., has a new electric light company.

Football by electric light is said to be the latest Philadelphia fad.

A new electric light company has been organized at Flemingsburg, Ky.

The Leesburg, Fla., Electric Light & Water Power company has been incorporated with a capital stock of $50,000.

The Hemp Electric Light Company [illegible] plant at West Toronto Junction, Canada. This company [illegible]

The litigation between the Rochester, N. Y., Electric Light company and [illegible] been settled by agreement [illegible] owners of water power [illegible] a dispute arose as to their rights on adjoining property.

ELECTRIC RAILWAY.

Work has been begun on the new electric street railway at Jackson, Mich.

Electricity will be used as the motive power of the Lake street railway of Waxahachie, Tex.

The West End Railway company of Savannah, Ga., has obtained a franchise to build an electric road.

It is stated that the Austin, Tex., Street Railway company will soon operate its lines by electric power.

It is proposed to build an electric road from Santa Barbara, Cal., through Montecito to the Hot Springs.

The Houston, Tex., City Street Railway company, which operates electric lines, will extend its system.

The Detroit Electrical Works are equipping in New England six street railway systems as follows: The Lawrence electric street railway at Lawrence, Mass.; the Black Rock & Salisbury Beach railway at Amesbury, Mass; the Augusta, Hallowell & Gardner electric street railway at Augusta, Me.; the Newburyport street railway at Newburyport, Mass, and the Gloucester street railway at Gloucester, Mass.

The Kanawha City and Charleston Electrical Railway company has been chartered in West Virginia for the purpose of building a railway line from Charleston to Kanawha City. The length of the line will be about two miles beside the turns about the streets of the two cities. The road will be operated by electricity, and will carry light freight and passengers. The company has a capital stock of $100,000, and will build as soon as possible.

ELECTRIC MINING.

A mining engineer of Sydney, New South Wales, has invented an electro-chlorination process for the reduction of gold ore.

MISCELLANEOUS.

The electric fountain at Lincoln park, Chicago, is in operation every Tuesday and Saturday evening.

Electricity is said to be the latest fashionable resource as a cure for tippling by wealthy men in Paris and London.

June electrical storms did considerable damage throughout the country. At St. Paul, Minn., on the 27th, lightning struck a car on University avenue, destroyed the line overhead and ruined the motor. A similar accident occurred on West Seventh street. The house of Peter Rusan, residing on Wyoming street, near Oakdale, was also struck. The current, descending the chimney, struck Mrs. Rusan, who was siting near it, and severely burned her down the head and neck and partially paralyzed her lower limbs. Two children who were on the floor were slightly burned. The house was considerably damaged. During the same storm at Archibald Malcom's farm near Oak Lake, Manitoba, a bolt of lightning killed a team of horses and a Frenchman standing near, while the driver was unhurt.

TRADE NEWS.

The excessively hot weather last week is what electrical people call "good fan weather." The Central Electric company reports large sales of motor fans. It keeps a variety of this class of goods for its customers to select from.

J. F. Hockett was appointed general manager of the Card Electric Motor & Dynamo company of Cincinnati, O., June 15th, in place of H. H. Walter, resigned. This company is reported to be in a most flourishing condition and it is contemplating increasing the factory facilities within the next sixty days.

Ingenious conceits and unctuous touches of humor characterize the advertising matter of the Electrical Supply company, Chicago, in a marked and pleasing degree. Several bright originalities of this character distinguish a recent circular setting forth the merits of the Shield Brand moisture proof wire This "dry subject" is handled in machine-made blank verse and with various diagrams and pictures, the whole making a unique combination.

The almost constantly increasing demand for a compact simple and economic arrangement for isolated electric lighting has led L. J. Wing & Co., of New York and Chicago, to introduce a combination of a Dake steam engine and a Riker dynamo, the former being a small high-speed engine and the latter a low-speed dynamo, and both mounted on a single base. The machine is especially adapted for use on locomotives for lighting trains, and at the same time for ventilating and cooling the cars with electric fans It is also valuable in lighting and ventilating yachts, steamships, factories, etc., requiring minimum care and attention, and giving maximum light for power used. It may be employed for arc and incandescent lighting, or for either separately, and is made [illegible] sizes corresponding to the power desired. The light produced by this arrangement is constant and steady.

A. D. Lundy, of the firm of Sergeant & Lundy, arrived from the East a few days since, and has taken [illegible]

work connected with the new enterprise. Mr. Lundy is well known in Chicago electrical circles, particularly in connection with electric street railway interests, having served for several years as chief engineer of the Sprague Electric Equipment company, during which time fourteen roads were built and equipped. During the past year he has been with the southern district of the Edison General company with headquarters at Atlanta. His connection with the early work of electric street railway building has given Mr. Lundy a valuable experience that will be of a special value to him in his present duties. Mr. Sargent needs no introduction in Chicago, having served a long apprenticeship with the Edison companies, and at present holding a responsible position with the department of construction of the World's Columbian Exposition as electrical engineer. The new firm is a strong one, and in the specialty which it purposes making prominent, that of the complete equipment of power plants, using the McIntosh & Seymour engines, its influence will undoubtedly be speedily felt.

BUSINESS.

The Cincinnati Engineering company is bringing out a new electric freight and passenger elevator that has many novel features, and which will undoubtedly attract attention when ready to be shown.

The Moore Electrical Manufacturing company, 652 and 654 Hudson street, New York, calls attention to its improved Leclanche Disque battery.

Louis Blatz, 103 West Monroe street, Chicago, is adding new machinery to his brass foundry, and when completed will have the best, or one of the best, equipped establishments of the kind in the city. Mr. Blatz will make a specialty of castings for electrical work.

The Cleveland Wheelbarrow Manufacturing company, Cleveland, Ohio, has purchased the business, including real and personal assets, of the Cleveland Wheelbarrow and Truck company. E. F. Wright has been succeeded by J. W. Hornsey, secretary and treasurer.

Some idea of the extent of the use to which the fan motor is being put for ventilating purposes can be gained from the fact that Jones Bros. of Cincinnati have over 300 in use on a central station circuit supplying 3,800 incandescent lamps and covering a radius of less than one half mile. All but a very few of these motors have been installed since May 1st. The demand for additional power has compelled them to put in a new 150 horse power Porter engine in order to get sufficient current during the day without running the large Hamilton-Corliss engine which they have in place for their customary work.

Geo. Cutter has had three teams during the past week constantly engaged in hauling weather-proof Simplex wire from his warehouse to the various freight depots for shipment. Mr. Cutter has also shipped direct from the factory during the past week a large slate switch-board for use in a Detroit theater that is being refitted. He is also receiving large orders for his new magnetic cut-out for railway use, 28 having been shipped recently to one road. Cutter's lamp supporting pulley is growing in popularity. It is claimed for it that it is thoroughly sleet-proof and will hold the lamp securely even if the hoisting rope slip.

The Union Electric Works, 506 Springer Building, Chicago, have recently added to the capacity of their factory, and are now ready to manufacture small electric appliances for the trade, or they will take special care in the developing of any electric device, and when the same is completed they will manufacture it on a royalty, or they are prepared to purchase it outright from the inventor. This company is provided with an able corps of electrical and mechanical engineers, who are fully competent to pass upon the value of any device or application offered, and it is believed that this department will prove of great benefit to young inventors and to any others that wish to dispose of their productions.

L. A. Spaulding, Chicago, has just secured letters patent on a decidedly novel application of the electric current. His device provides for the playing of a game of pin pool on an ordinary pool table, minus the pins, and [illegible] of the count in a game of ball pool. In the former game sensitive push buttons are arranged in the center of the table under the spots usually occupied by the pins, and the balls, in passing over them, [illegible] which is recorded by an ordinary annunciator placed for convenience in the wall near [illegible] table the butters are arranged in front of the pockets, the count being shown in the same manner. The invention is certainly novel, and will undoubtedly attract attention.

[illegible] company is showing some very [illegible] Okonite cable. The [illegible] has increased so lately that [illegible] to go into its manufacture [illegible] the product in the West [illegible] which is the general [illegible] secured some flattering contracts and will soon be in the field as an active [illegible] company [illegible] and better it [illegible] E. [illegible] of [illegible] contracts for [illegible] at [illegible]

S. Merrill, C. H. Sewall and R. B. Cone. The company is engaged solely in the business of furnishing steam and electric equipment materials. No construction work is attempted, although the lowest figures can be obtained for the construction of steam power plants and electric railways. The Engineering Equipment company has its chief offices in the Central building, 143 Liberty street, New York. It is the sole eastern selling agency for patent cotton leather belting and belting specialties, manufactured by the Underwood Manufacturing company, and for the Boston trolley and line materials, made solely by Albert & J. M. Anderson. It has also the United States and Canadian selling agency for the indurated fibre pipe, produced only at Mechanicsville, N. Y., and for the Kellogg steel center and side poles made by the Kellogg Iron Works of Buffalo, N. Y.; also Eastern selling agents for Habirshaw wire, cables and cores, and general agents for the machine tools manufactured by Edward Harrington, Son & Co. Many large orders have been filled by the company to the complete satisfaction of customers.

ELECTRICAL PATENTS.

Issued June 23, 1891.

454,450. Brake Mechanism for Street Cars. Norman C. Bassett, Lynn, Mass.

The last claim follows:

"7. The combination of a truck having an electric motor geared and supported thereon, so that the tractive power of the wheels upon the different axles is rendered unequal, with brakes for both sets of wheels, and a pull rod or chain connected at one end to the brake apparatus for the loaded wheels and at its other end to a lever connected both with the truck-frame and a brake apparatus for the light wheels and means for adjusting the connection of the rod relatively to the lever for varying the braking pressure applied to the last named wheels."

454,462. Electric Elevator. Rudolf Eickemeyer, Yonkers, N. Y.

454,467. Belt Controller for Dynamos. William A. Foote, Battle Creek, Mich.

454,470. Signal Device for Telephone Pay Stations. William Gray, Hartford, Conn.

454,475. Electric Regulator for Constant Potential. Carl Hering, Philadelphia, Pa.

454,476. Electric Regulator for Constant Potential. Carl Hering, Philadelphia, Pa.

454,485. Electric Arc Lamp. Herman Lemp and Merle J. Wightman, Hartford, Conn.

In this lamp the arc is formed by the main circuit magnet, which, as soon as the arc is formed, no longer plays any part in the operation of the lamp, the actions thereafter being under the control of the derived circuit magnet.

454,486. Overhead Electric System. Charles A. Lieb, New York, N. Y.

454,487. Car House Hanger. Charles A Lieb, New York, N. Y.

454,488. Commutator for Dynamos or Motors. Charles A. Lieb, New York, N. Y.

This invention consists in the combination of commutator bars or sections containing aluminum and a brush of carbon. The sections of aluminum will not alter in size materially when heated or cooled, consequently the sections or bars will not become loosened.

454,496. Limit Switch. Frank B. Rae, Detroit, Mich., assignor to the Detroit Electrical Works.

454,500. Mining Machine. Elmer A. Sperry, Chicago, Ill.

454,503. Signal Attachment for Telephones. Alfred D. Sundeen, Swan B. Molander and Gustaf W. Anderson, Mora, and Andrew M. Carlsen, St Paul, Minn.

454,504. Signal Attachment for Telephones. Alfred D. Sundeen, Swan B. Molander and Gustaf W. Anderson, Mora, and Andrew M. Carlsen, St Paul, Minn.

The first of the seven claims reads:

"The combination, with a telephone, of a phonograph and an electro-magnet connected in the circuit of the telephone for releasing the phonograph by passing an electric current over the line from other stations, means for conducting the sound of the predetermined speech from the phonograph to the transmitter of the telephone to which the phonograph is attached, and means for stopping the phonograph after it has given the distant station the predetermined information."

454,522. Trolley Pole Mechanism. George H. Larkin and James Tomkins, St Paul, Minn.

454,529. Coin Freed Weighing or Similar Machine. George E. Rutter, London, England.

454,532. Trolley for Railway Cars. Edmond Verstraete, St. Louis, Mo.

454,536. Electric Car Trolley. William Duncan, Allegheny, Pa.

454,541. Speed Regulator for Dynamo Electric Machines, Erastus L. Winkley, Lynn, Mass.

454,546. Electric Conductor. Alfred W. Sperry, Hartford, Conn.

454,547. Insulating Material. Alfred W. Sperry, Hartford, Conn.

454,548. Composition for the Manufacture of Insulators, Packings, etc. Alfred W. Sperry, Hartford, Conn.

454,555. Magnetic Separator for Paper Pulp. Charles H. [illegible], Lynn, Mass.

To the upper surface of the bottom of the trough is applied one or more metal bars which extend across the trough from side to side, and which are connected [illegible] with the trough. The pulp in flowing through the trough is opposed in its passage by the magnetized bars and the iron particles are then separated.

454,558. Incandescent Electric Lamp. Thomas A. Edison, Menlo Park, N. J.

Between the leading in wires is sealed a third, which extends and is attached to the center of the carbon by electroplating thereto. The current is divided between the two limits of the carbon, thus causing the latter to be in multiple arc.

454,570. Walking Automaton. George R. Moore, Westford, Mass.

454,573. Electrical Pessary, Walter N. Sherman, Merced, Cal.

454,584. Switch-board for Telegraph Lines. Frank T. Viles, Hyde Park, and Nicholas Young, Boston, Mass.

454,598. Galvanic Battery. Philip Hathaway, New York, N. Y.

454,604. Electric Search Light. Gaston Sautter, Paris, France.

454,622. System of Electric Lighting. Nikola Tesla, New York, N. Y.

Claim seven reads:

"In a system of electric lighting, the combination, with a source of currents of enormous frequency of excessively high potential, of lighting devices, each consisting of a conducting body inclosed in a rarefied or exhausted receiver and connected by conductors directly or inductively with one of the terminals of said source, all parts of the conductors intermediate to the said source and the light giving body being insulated and protected to prevent the dissipation of the electric energy."

454,625. Electric Signal for Railway Trains. Francis P Lenahan, Wilkesbarre, Pa.

454,626. Electric Motor. Frank B. Rae, Detroit, Mich.

This invention provides for an automatic switch that shall operate to break the connection between the main line and the motor in the event of any interruption or variation of the circuit.

454,627. Electric Motor. Alexander B. Roney, Chicago, Ill.

This motor is a combination of two or more auxiliary motors placed upon arms at right angles to the driving shaft. These auxiliary motors are adapted to travel around the plane of a circle, and upon a circular field magnet by means of rubber wheels attached to the radial arms and bearing against said field magnet. The rate of speed is controlled by a network of levers, which thrust the auxiliary motors out or draw them toward the center, thus diminishing or increasing the speed.

454,630. Telegraphy. Benjamin C. Toye, Toronto, Canada.

454,643. Electric Signal-Receiving Instrument. George L. Foote, Brooklyn, N. Y.

454,650 Regulating Electric Lights and Power. Isaac Herzberg and Abram Herzberg, Philadelphia, Pa.

454,669. Electric Hose Coupling. Joseph B. Strauss, Cincinnati, Ohio.

454,671. Lightning Arrester. Elihu Thomson, Swampscott, Mass.

454,672. Lightning Arrester. Elihu Thomson, Lynn, Mass.

454,673. Lightning Arrester. Elihu Thomson, Swampscott, Mass.

454,698. Method of an Apparatus for Heating Bars by Electricity. Edwin E. Angell, Somerville, Mass.

In this mode a metallic bar or blank is inserted in a circuit, then another is inserted in parallel in the same circuit, side by side with the first blank, and then withdrawing one of said bars from said circuit, the other bar or blank remaining in circuit during such withdrawal.

454,717. Insulator for Marine Condensers. Peter Decker, Norwalk, Conn.

454,724. Galvanic Battery. Julius Emmner, Jr., Washington, D. C.

454,746. Electrical Fire Alarm. Brunswick W. Leonard, Saybrook, Conn.

454,782. Lamp Cut-out and System. Elihu Thomson, Lynn, Mass.

We quote claim three:

"The combination with an incandescent electric lamp of an auxiliary normally idle wire or conductor extending into the vacuous or exhausted receiver, which contains the incandescing conductor of the lamp and connected outside of the lamp with the circuit thereof, and a cut out device for short-circuiting the lamp, operated by the passage of an abnormal current in said idle wire or conductor upon rupture of the filament or incandescing conductor."

454,794. Electric Connection. John H. Bickford, Salem, Mass.

454,815. Electric Light Hanger. George W. Smith, Union City, Ind.

454,816. Electric-Circuit Closer. John H. Ward, New York, N. Y.

454,818. Electrode for Secondary Batteries. Boyd Anderson, Texarkana, Tex.

454,832. Electro-Magnet Clutch. Erastus S. Bennett, Denver, Colo., Horace F. Parshall, Baltimore, Md.

In this device, electro-magnetic force or attraction is made to arrest motion having the function of a brake or to transmit motion, the power acting in each case without the interposition of friction

EUGENE F. PHILLIPS, President. W. H. SAWYER, Sec'y and Electrician.

AMERICAN ELECTRICAL WORKS,

PROVIDENCE, R. I.

FARADAY CABLES.

New York Office, 10 Cortlandt Street,

P. C. ACKERMAN, Agent.

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and **is guaranteed to be waterproof, and will not deteriorate, oxidize or crack,** and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

JUNE, JULY AND AUGUST.

The most charming Summer Resorts, of which there are over three hundred choice locations, are to be found in Wisconsin, Iowa, Minnesota, South Dakota and the Peninsula of Michigan, along the lines of the Chicago, Milwaukee & St. Paul Ry. Nearly all are located near lakes which have not been fished out.

These resorts are easily reached by railway, and range in variety from "full dress for dinner" to the flannel shirt costume for every meal.

SEPTEMBER AND OCTOBER.

The finest shooting grounds in the Northwest are on and tributary to the lines of the Chicago, Milwaukee & St. Paul Ry. The crop of Prairie Chickens will be exceptionally good this year; also Ducks and Geese. In Northern Wisconsin and the Peninsula of Michigan splendid Deer shooting is to be had.

Full information furnished free. Address GEO. H. HEAFFORD, Gen. Pass. Agt., Chicago, Ill.

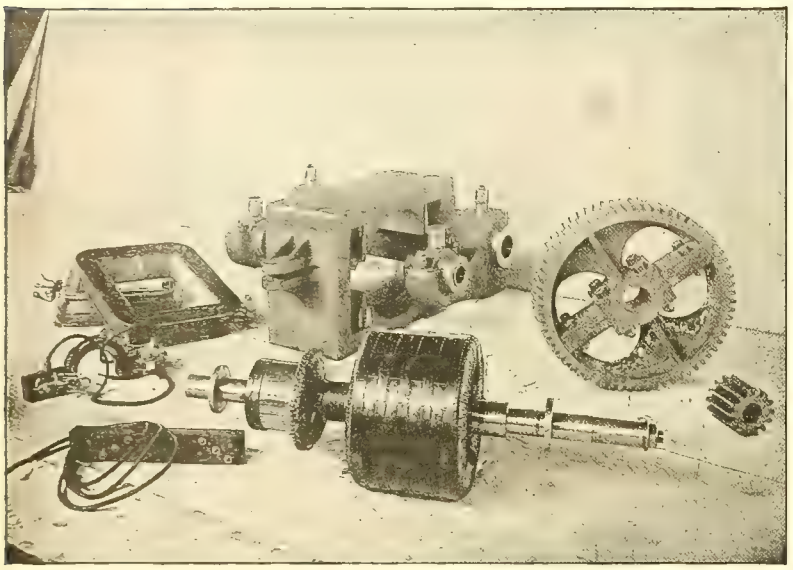
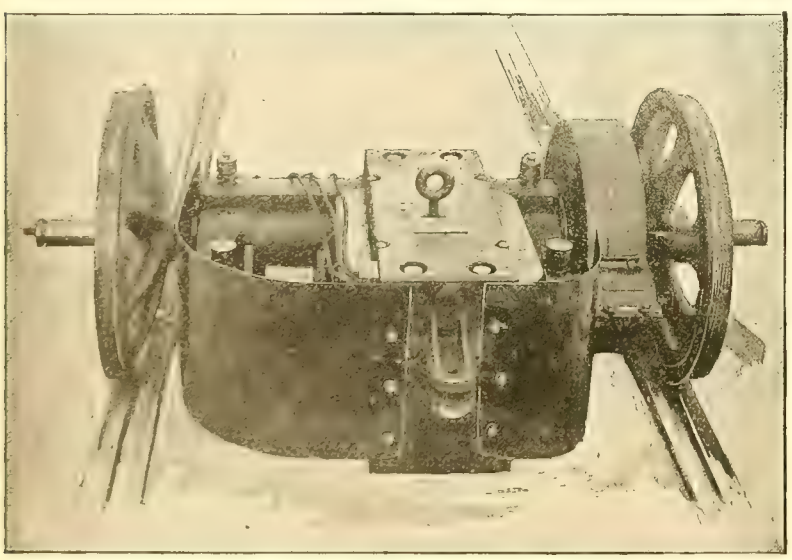
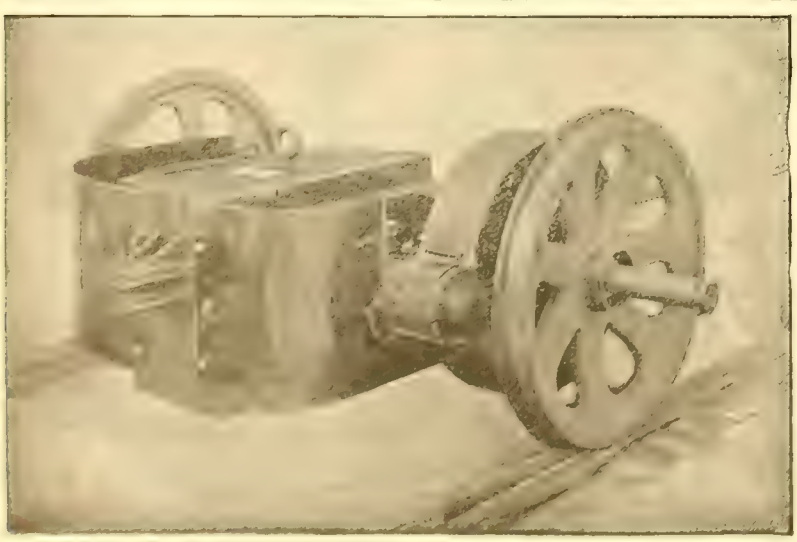
A MARVELOUS INNOVATION

THE THOMSON-HOUSTON ELECTRIC COMPANY

Has Revolutionized the Electrical Equipment of Street Railways.







The Intermediate Shaft, Pinion and Gear have been discarded.

The Armature Pinion and Axle Gear are now enclosed in a dust-proof case filled with oil.

Reducing to a minimum the cost for repairs and absolutely eliminating the objectionable noises incident to all other systems.

The Armature speed has been reduced from 1200 to 500 revolutions per minute.

The Railway Motor, as now constructed, comprises less than a dozen parts.

The construction of the Armature avoids the possibility of a burn-out, except by malicious carelessness, and when damaged, can be readily repaired by a novice.

Don't make a mistake by contracting for Railway Equipment before seeing or understanding this marvelous machine.

Prices for Repairs, Parts and Supplies materially reduced.

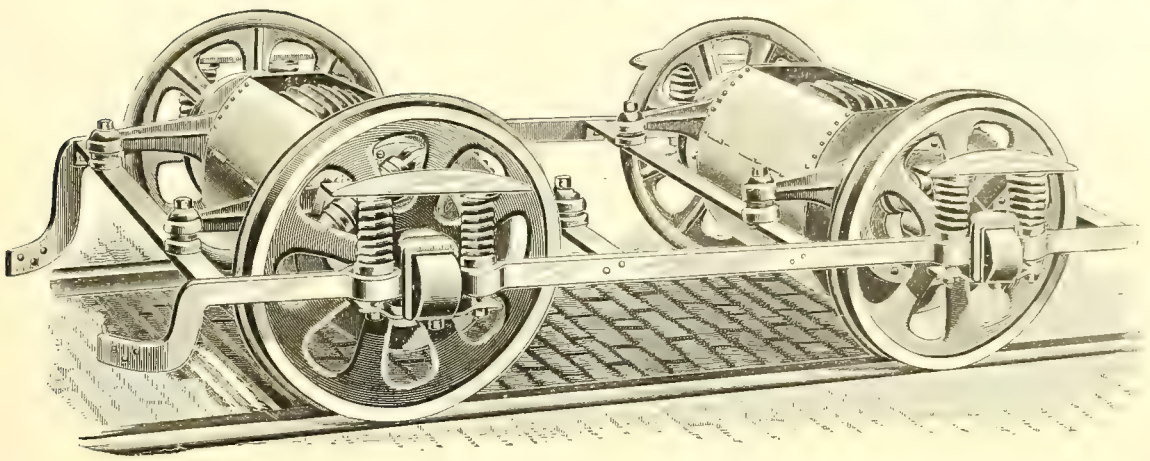
Information, Prices and Literature furnished on application.

Thomson-Houston Electric Co.

CHICAGO OFFICE:
148 Michigan Avenue.

BOSTON OFFICE:
620 Atlantic Avenue.

NO GEARS.
NO NOISE.
NO REPAIRS.



We have ELIMINATED from the street railway motor

ALL gears and pinions.
ALL armature and intermediate shafts.
ALL brass bearings, except the axle brasses.
ALL oil cups.
ALL box caps.
ALL useless nuts and bolts.
ALL mud and dust pans.
ALL dust curtains.
ALL hanger bars and bolts.

The motor is supported entirely upon springs, thus preventing the hammer blow, which flattens rail joints and loosens fish plates.

IT WILL SAVE YOUR TRACKS.

The speed of the motor armature has been reduced from 1,000 to 100 revolutions per minute, and the weight of the motor is not increased.

"AND DID THAT EVER OCCUR TO YOU?"

The superintendent of a United Electric Light and Gas Co. was much annoyed on account of the gathering of moisture in his gas pipes, causing partial, and at times entire, stoppage of gas flow. One day one of his electric light customers complained, through the telephone, that his lights wouldn't work. The superintendent replied, "Better get a plumber; your wires must be full of water."

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, unequaled for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Correspondence solicited from all manufacturers and dealers in electrical machinery and supplies. SEND FOR PRICES AND ESTIMATES.

For Sale by THE CENTRAL ELECTRIC CO., CHICAGO.

To Electric Railway Companies:

We shall be pleased to make you quotations on Washburn & Moen's hard drawn copper trolley wire, and our own make of Weatherproof insulation feeder wires. Our Weatherproof wire is superior to any other wire of like character in the market.

WESTERN ELECTRIC COMPANY, CHICAGO. NEW YORK.

Vol. IX. CHICAGO, JULY 11, 1891. No. 2

The First Electric Pipe-Welding Plant in Chicago.

From the accompanying views there may be obtained a good idea of the general arrangement of a pipe welding plant which has been recently installed by the Thomson Electric Welding company, in the factory of the Marinette Iron Works, Chicago. This plant which was started a few weeks ago, is the first one of the kind to be put into practical operation in Chicago and is said to be the fourth pipe welding installation in the United States.

The equipment is used to join 1¼ inch and 2 inch extra heavy iron pipe. At the present time the apparatus is applied in the work of welding 2 inch pipe for cold storage and ice machines, the Marinette company having a large contract for the Cold Storage Exchange, Chicago.

The views presented herewith show the current generating plant and the welder in practical operation joining the sections of the coils.

Besides the apparatus just mentioned there is a portion of the equipment which does not appear in the cuts. The outfit referred to is in reality a part of the welder proper, but in this case it is placed on the wall across the room from the welding machine. This apparatus consists of a reactive coil for regulating the current in the welding circuit, a make-and-break switch which is operated by a light wire cable leading from a treadle at the welder, a register in which is recorded the number of welds made and the usual fuse boxes and switch.

The view of the engine room, Fig. 2, was taken through the open window from the outside of the factory. The engine room is built into the shop; that is, it is partitioned off from it so that the machinery within is entirely inclosed by glass windows. By this construction the engine, etc., is in reality in a separate and distinct apartment. This room contains the 100 horse power Atlas engine which drives the main line shaft of the works and is also belted directly, as shown, to the welding generator. In addition to the engine and dynamo there is also in the room a complete switch-board for the welder. The switch-board is shown to the left in the illustration.

The generator which supplies current for the welding, is a 30,000 watt machine built to deliver current in the primary of the welder at a potential of about 300 volts. The maximum primary current which the machine may be called on to deliver is about 150 amperes. This dynamo is of the same general design as the machine usually employed by the Thomson Welding company in connection with its other welding equipments. It is a multipolar machine, and is over compounded to about 15 per cent. It is self-exciting.

The welder proper is of the type described by the Thomson Welding company as their "pipe machine." It has a capacity from the smallest sizes of pipe up to 2 inch pipe.

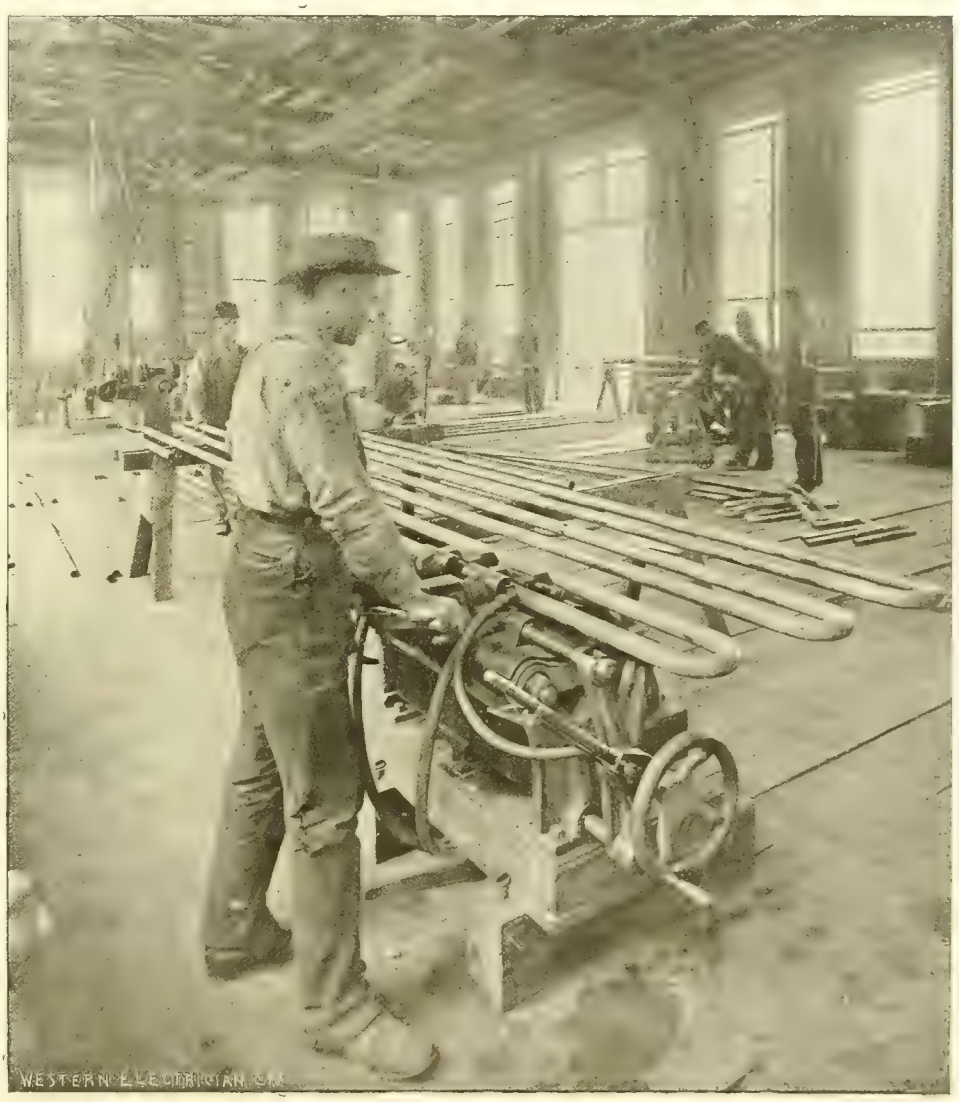

FIG. 1. FIRST ELECTRIC PIPE-WELDING PLANT IN CHICAGO.

As used in this company's works, the machine requires for its most successful operation, the services of three men. One man and a helper make the welds on the machine and another workman is employed with a file in preparing the ends of the pipe.

As this machine was only started a few weeks ago, the company, while feeling confident that a great saving is effected through its use, is as yet unable to give any accurate data relating to the machine's performance. From the point of good workmanship, however, the company is well satisfied with the electrical method. The welds can be made each in about 15 seconds, but the average number of welds in a day's work owing to the time taken up in handling the material, is about 225. It is estimated that an average of 55 horse power is required to weld the 2 inch extra heavy pipe upon which the company is now working.

It may be mentioned that all the coils are tested after having been welded, with an air pressure of 500 pounds to the square inch. The test is made with the pipe under water, the air being applied to the coils while they are submerged. By this means any leak may be detected by air bubbles rising to the surface of the water. When the machine was first started a special test was made in which an air pressure of 800 pounds was employed. Eight short pieces of pipe were welded together in the usual manner but the closest scrutiny failed to reveal that the pipe was otherwise than absolutely tight at all the joints.

Electrical Department, World's Fair.

Lumber is already on the ground at the site of the electricity building in Jackson Park, and it is probable that building operations will be begun immediately on this as well as the Mines building. Some delay has been caused by the dispute with the Illinois Central Railroad company as to the price to be paid per carload for hauling freight and material to the grounds, but the indications are that this difference will be speedily and satisfactorily adjusted, and that the contractor will soon have a large force of men at work.

The planning of the permanent electric lighting arrangements at the grounds and buildings at Jackson Park is still under advisement by the departments of electricity and construction, and will be, of course, for some time to come. The present idea is to defer actual work on the general scheme until representatives of the two departments—probably Chief Barrett and Mr. Sargent—shall have returned from a visit to the East for the purpose of conferring with the big electrical companies on the subject. It is proposed, if possible, to give every company in the country manufacturing electric lighting plants a chance to do a portion of the work in connection with its exhibit. It is thought that some arrangement of this sort can be made if the various exhibitors will enter into the spirit of the plan and co-operate in friendly rivalry. Prof. Barrett will make an earnest effort to bring about an understanding of this kind. He expects to start at once on his tour of investigation.

Bids for the work and material necessary for the temporary lighting installation at the World's Fair grounds will be opened July 13th.

The Field Engineering company of New York has applied for 625 feet of space in the electrical building.

Electrical Engineer Sargent of the Construction Department has a plan for an electrical fountain at the exposition, which, if carried out, can hardly fail to result in one of the greatest popular attractions of the fair. The fountain is to rise from the water of the lagoon, near the administration building, with a basin 100 feet in diameter. A beautiful design for the structure itself has already been proposed by an eminent eastern sculptor, and Mr. Sargent's plan has to do purely with the electro-scenic effects on the water. The fountain will be very much larger than the one at Lincoln Park and finer in every way. The principle employed will be different, depending upon the use of hollow nozzles, by which the light is thrown into the water from the middle of the jet itself. It is proposed to introduce the water into one-half of the basin through large entry pipes that will have the appearance of spouting forth great streams of different colored liquids. On the other side the water will flow back into the lagoon, over the edge of the basin, in one unbroken cascade. Back of this sheet of water incandescent lamps with globes of different colors will be placed, which will produce a very beautiful effect.

Water lilies, with little lamps taking the place of blossoms amid the dark green leaves, will float on the surface of the water and queer phosphorescent fish, electrically illumined, can be seen in the quiet depths. Other novel features are proposed, and Mr. Sargent is confident that the fountain could easily be made to surpass anything of the kind ever attempted.

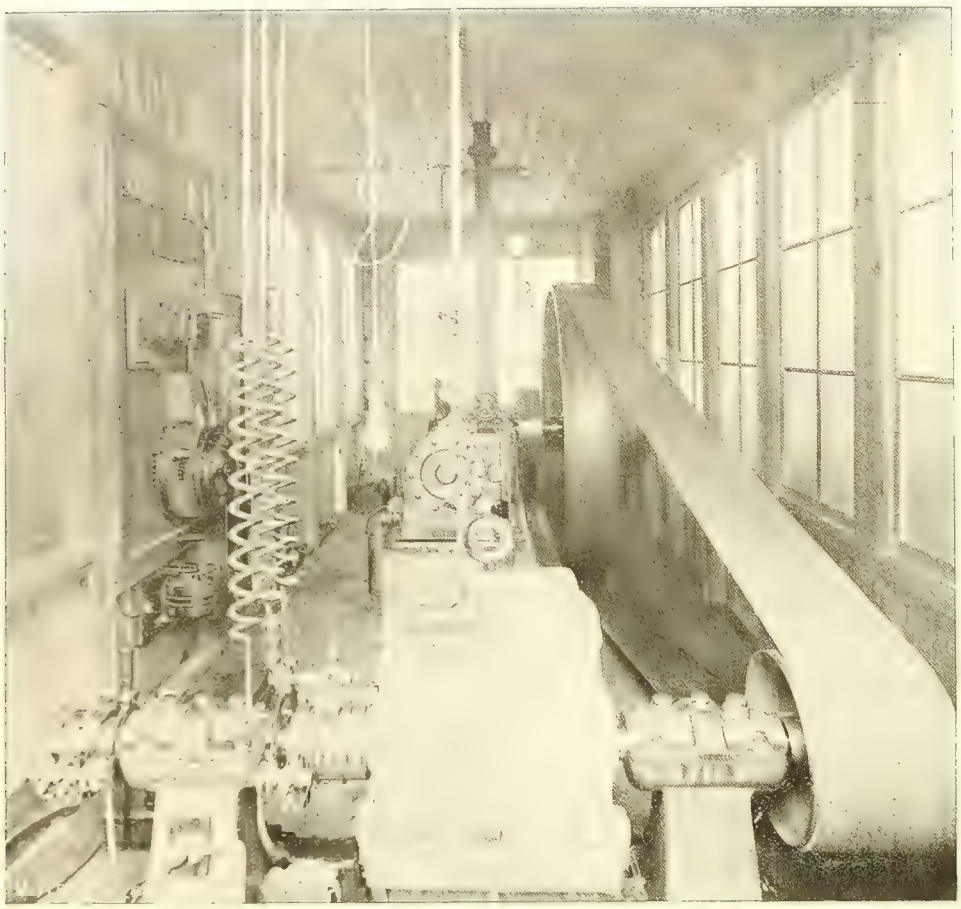

FIG. 2. FIRST ELECTRIC PIPE-WELDING PLANT IN CHICAGO.

Before long arrangements will be made for complete fire alarm and police patrol telegraphic service on the exposition grounds.

Controversy over a Franchise.

According to the Chicago daily papers several city officials have been worrying over the complaint made by a member of the city council at a committee meeting last week. A sub-committee was appointed to investigate the relations between the Chicago Arc Light & Power company and the Archer Electric Light company. The charge was made that the former company had violated the terms of its franchise in renting its conduits to the Archer company.

B. E. Sunny, when called upon by a representative of the WESTERN ELECTRICIAN, stated that the Chicago Arc Light & Power company had a perfect right to sub-let its conduits, and that its dealings were fair and above board. Mr. Wilmerding, the secretary of the Arc Light company, when called upon, stated that the company was bound by the franchise to permit any company [illegible], charging it a reasonable rate. If the contracting company regarded the rate as too high, they had the right to demand the appointment of a board of arbitration. The Archer company had made no com[illegible] such demand. "Had the council committee examined the franchise," said Mr. [illegible] company was [illegible] following out [illegible] with the Archer [illegible] and I [illegible] to create [illegible] company, which is [illegible]

Experiments on the Zipernowsky Electric Railway with a Vertical Track.

The following is a description by a correspondent in the London *Electrical Review* of the first experiments at the Buda Pesth Wagon Works on the Zipernowsky vertical track electric tramway.

This trial line was designed to represent all the conditions which occur on a tramway, and thus test the applicability of the system.

To this end there was laid down a curve of 90°, and of 20 meter radius, and further a counter-curve of 30 meters radius without a straight transition piece, as also a complete shunt consisting of two changes with a length of 42 meters between the points.

The trial line is level, but both in the straight parts and in the curve there are short portions of the track with an in[illegible]

As carried out in the present instance the surface which gives off the current is horizontal. The upper surface of the rails is also coated with a peculiar substance, which insulates and also prevents metallic particles which might be accidentally introduced through the slit of the rails into the interior of the channel, from occasioning a short circuit.

The rails weigh 23 kilos per meter, and the guide-rails 10 kilos.

The upper structure is in part completely walled in, but a portion is merely screwed to the sleepers which, are bedded in sand. This was done in order to observe the operation of the mechanism in the channel during the journey.

The most essential part of the car, namely, the plate extending through the slit between the rails into the interior of the channel, consists of wrought cast steel of the thickness of 25 to 27 mm.

This plate carries at its lower end two guide rollers fixed at a distance of 10 mm. from each other, which run on the guide rails of the car. A little above these rollers there are sliding contacts on each side of the plate, which constantly press upward against the surface of the current-rails.

The car consists of two turning supports set at a distance of 3 meters apart. The sliding contacts are eight in number, four on each current rail. By this arrangement the advantage is secured that if one pair should accidentally find no contact, the upper pair would take up the contact at a distance of 3 meters, before or behind.

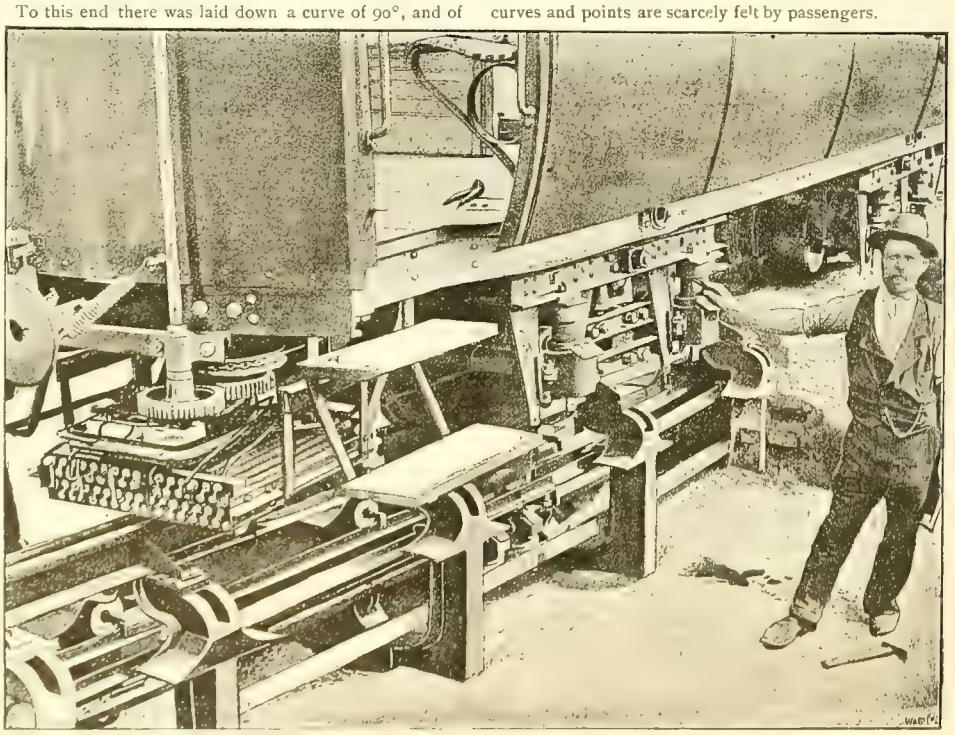
Each rotating support consists of two wheels, one only of which is driven by the motor. Hence the car has two running and two driving wheels. The wheels are set vertically. The action of the motors upon the axles is effected by means of a worm and gear. The worm is keyed upon the shaft of the motor, and the worm wheel is bolted upon the driving shaft.

The box of the car is 1,600 mm. in breadth and 5,000 mm. in length, containing three compartments with 24 seats. The middle compartment is partitioned off, and there are besides six seats at the front end of the car. Here there is also a platform of 1,000 mm. in length, from which both motors can be attended to and regulated by means of a hand brake.

The trial trips, it is claimed, proved that this system was especially suited for electric lines in narrow streets with an underground supply of current.

Both in the straight lines and in the curves and at the points a speed of 10 kilometers an hour was attained, and it could easily be doubled on a longer line.

The movements of the car are extremely smooth. No shocks are perceptible, and the operations of passing curves and points are scarcely felt by passengers.

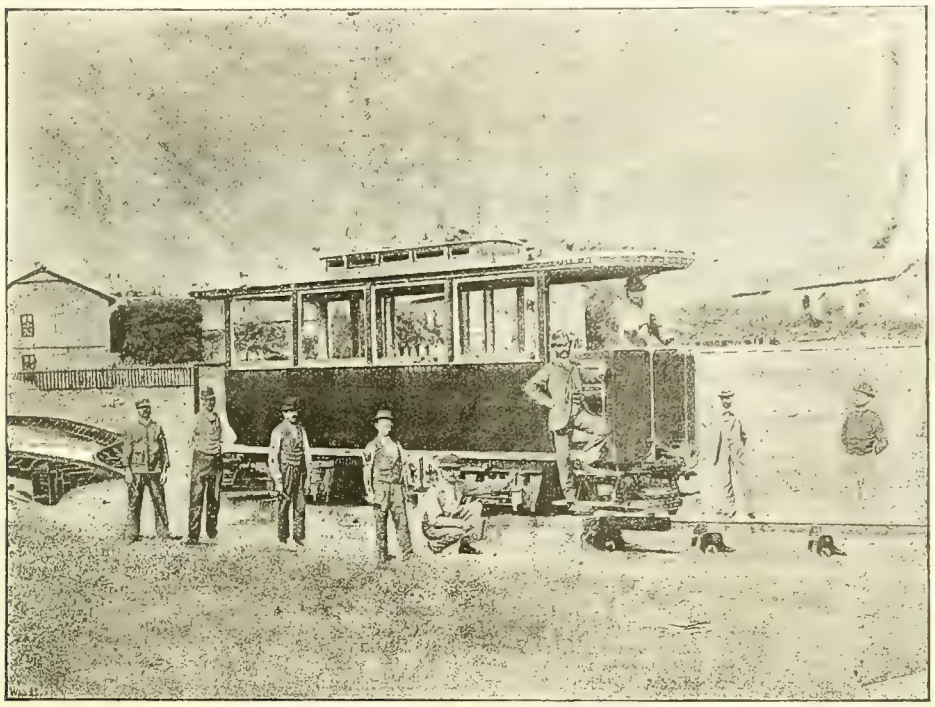


ZIPERNOWSKY'S ELECTRIC RAILWAY WITH VERTICAL TRACK.

Measurements undertaken to test the steadiness of the car showed that in the parts not walled in, and especially at the parts where the distance of the running rails and guide rails had not been quite accurately adjusted (which was done purposely) the highest point of the oscillations of the car did not amount quite to 50 mm in a horizontal direction. On other tramways, even those with a normal track, such oscillations are very frequent, and have not

been obviated. The oscillations are chiefly occasioned by the circumstance that the structure was not walled in but merely bedded in sand, and that therefore the elasticity of the sand and of the legs of the chairs came into full play. At parts where the line was walled in and paved, the oscillations did not exceed 30 mm.

Vertical oscillations were not observed, probably because



ZIPERNOWSKY ELECTRIC RAILWAY WITH VERTICAL TRACK.

the car was built without springs. Nevertheless, the movements of the car were gentle, and vibrations generally felt in cars without springs were evaded by placing india-rubber rings under the supports of the car.

Trial trips were made with the car loaded on one side, but no changes were observed either in the upper structure or the cars, and especially not in the guide plates, which were loaded with 20 kilos. per square mm.

The working of the points (in which a spiral spring now serves instead of a counterpoise to bring back the points to the normal position) is faultless. It is asserted that an automatic system of changing from one line to another can be used. The passage of current through both changes is almost continuous.

To render it practicable for a car to turn into the left hand track instead of into the right-hand, a setting arrangement, worked by hand, has been provided at the lower tongue of the point.

The cuts will doubtless aid the reader in obtaining an idea of the construction of the system.

Pole Chopping in New Orleans.

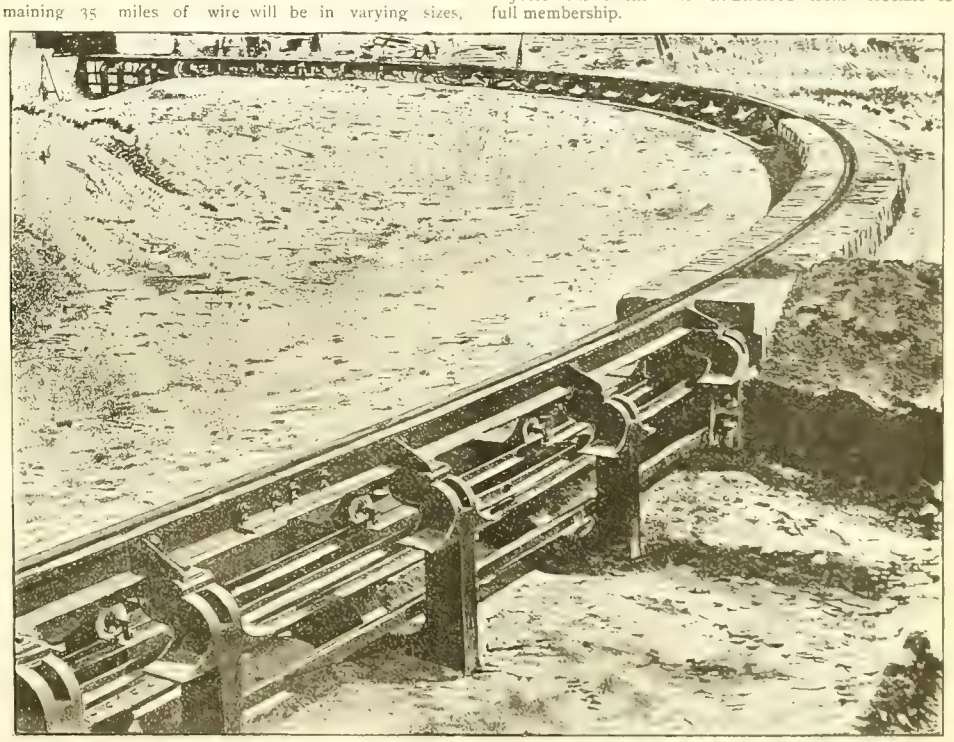
Belligerent councilmen have introduced the pole chopping craze in New Orleans. A press dispatch gives this account of the affair:

When the council recently granted the Postal Telegraph & Cable company the right to enter the city it was stipulated that it should either use the poles of other companies or construct an underground cable. The company did not, at the time, give its consent to this arrangement, and instead of utilizing the cable privilege in its grant again applied to the council for permission to erect poles. The council, without even hearing the Postal Telegraph people, refused the request. On Monday of last week the company put up a line of poles and strung two wires to its office. The council at once ordered an investigation, and, should the report prove true, instructed the mayor to tear down the poles. No report was expected until Friday night, and the telegraph company expected to take out an injunction. Chairman A. C. Landrey, of the streets and landings committee, who had charge of the investigation, filed his report on Thursday and with it a request that the mayor carry out the council's order. Half an hour afterward the mayor had the poles chopped down against the protest of the Postal Telegraph company and before it could appeal to the courts. It will make a strong appeal. Mayor Shakespeare says that he carried out an order to which he is opposed. The action of the council disgusted him and seemed to say that the right to erect poles belonged to only a few people of the council's choice. He wants the people to find out how the council is working against their interests and so carried out the order, believing that the result will be to place the council in such a position before the public that the latter will see clearly what is going on.

The workshops and yards of the Intercolonial railway at Moncton, N. B., are to be lighted by electricity. The Wood arc lighting system will be used.

Underground Wires at Minneapolis.

Much interest has been excited among the member of the electrical fraternity in the Northwest by the elaborate system of underground construction contemplated by the Minnesota Brush Electric Light company of Minneapolis. About 85 miles of cables will be needed, as the company's wires will be put underground in all the business section of the city, as well as in a considerable portion of the resident district. This will be the most extensive system of underground street construction for electric wires ever attempted, and the cost is estimated at $100 000. Of the conductors required some fifty miles will be No. 5 B. & S. wire for arc lights and series motors. The remaining 35 miles of wire will be in varying sizes,



ZIPERNOWSKY ELECTRIC RAILWAY WITH VERTICAL TRACK.

from 250,000 circular mils down, and will supply current for alternating incandescent lamps and constant potential motor service. The conduits, with the necessary manholes, are all laid at present, and the wiring contract will include drawing in, jointing, special junction boxes and about 100 terminal heads at street lamps, and at centers of distribution at block centers. Naturally all of the companies supplying underground cables are anxious to get this large contract. The following named companies have put in bids: Standard Underground Cable company, Electrical Supply company (Habirshaw), Knapp Electrical Works (Safety), Central Electric company (Okonite), John A. Roebling's Sons company, Western Electric Company, [illegible] where.

American Institute Electrical Engineers.

At the meeting of the council of the American Institute of Electrical Engineers, the following delegates were appointed to attend the Frankfort Electrical Conference in accordance with a resolution adopted at the general meeting, May 21st: Carl Hering, [illegible] Heinrich, Nikola Tesla, Dr. E. L. Nichols. Prof. Heinrich is already in Europe and Mr. Hering [illegible] Normannia.

The following named associate members were elected:

John H. Barnard, general manager Asheville Street Railway company and Asheville Light & Power company, Asheville, N. C.

Henry B. Cram, treasurer Bernstein Electric company, 175 Prospect street, Cambridgeport Mass.

Frank L Dame, superintendent Vancouver Electric Railway & Light company, Vancouver, B. C.

Charles Edward Emery, consulting engineer 22 Cortlandt street, N. Y.

Thomas J. Fay, Maine Electric Improvement company, 136 Liberty street, N. Y.

Walter C. Fisk, manager Bernstein Electric company, 620 Atlantic avenue, Boston, Mass

John L. Gans, superintendent and electrician, the Electric company, Connellsville, Pa.

Warren B. Hadley, superintendent wiring department Edison Electric Illuminating company, 431 Fifth avenue, New York.

Louis W. Healy, The Wightman Electric company, 1205 Marion street, Scranton, Pa.

James W. Kellogg, assistant to district engineer, Edison General Electric company, 149 E. 25th street, New York.

Thatcher T. P. Luquee, assistant in surveying and practical mining, and student in electrical engineering, Columbia College, N. Y. and Bedford, N. Y.

Thomas Reeve Roseburgh, lecturer in electrical engineering, School of Practical Science, Toronto, Ont.

Giles Taintor, assistant electrician, N. E. Telephone & Telegraph company, 7 Walnut street, Boston, Mass.

Herbert C. Wirt, electrician marine department, Thomson-Houston Electric company, 12 Millmont street, Roxbury, Mass.

Francke L. Woodward, student in electricity, 49 Grand street, Albany, N. Y.

Jesse M. Smith was transferred from associate to full membership.

No further meetings of the Institute will be held until September.

A search light for railway purposes was tested recently by the electrician of the Jersey Central railroad. One Huntington light of 3,200 candle power was mounted on the switch signal bridge, 20 feet above the track. It is said that when turned on a station building one-third of a mile away even the outlines of the bricks could be distinctly seen; when turned on the track, the ties could be seen in front of the same station. Colors were plainly distinguished at a half mile distance. At [illegible] feet it would enable an engineer to tell the position of switches. The reflector was parabolic like those of locomotive headlights and silver plated and highly burnished.

Experiments with Alternate Currents of Very High Frequency and Their Application to Methods of Artificial Illumination.[1]

By Nikola Tesla.

Of all the forms of nature's immeasurable, all-pervading energy, which ever and ever changing and moving, like a soul animates the inert universe, those of electricity and magnetism are perhaps the most fascinating. The effects of gravitation, of heat, and light, we observe daily, and soon we get accustomed to them, and soon they lose for us the character of the marvelous and wonderful; but electricity and magnetism, with their singular relationship, with their seemingly dual character unique among the forces in nature, with their phenomena of attractions, repulsions and rotations, strange manifestations of mysterious agents, stimulate and excite the

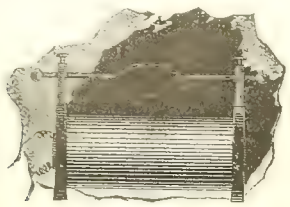


Fig. 4.—Sensitive Thread Discharge

mind to thought and research. What is electricity, and what is magnetism? These questions have been asked again and again. The most able intellects have cease lessly wrestled with the problem; still the question has not as yet been fully answered. But while we cannot even to day state what these singular forces are, yet we have made good headway toward the solution of the problem. We are now confident that electric and magnetic phenomena are attributable to ether, and we are perhaps justified in saying, that the effects of static electricity are effects of ether under strain and those of dynamic electricity and electro-magnetism effects of ether in motion. But this still leaves the question as to what electricity and magnetism are, unanswered.

It is not with the object of advancing an opinion, but with the desire of acquainting you better with some of the results, which I will describe, to show you the reasoning I have followed, the departures I have made—that I venture to express, in a few words, the views and convictions which have led me to these results.

I adhere to the idea that there is a thing which we have been in the habit of calling electricity. The question is, What is that thing; or, what of all things, the existence of which we know, have we the best reason to call electricity. We know that it acts like an incompressible fluid; that there must be a constant quantity of it in nature; that it can be neither produced nor destroyed; and, what is more important, the electro-magnetic theory of light and all facts observed teach us that electric and ether phenomena are identical. The idea at once suggests itself, therefore, that electricity might be called ether. In fact, this view has in a certain sense been advanced by Dr. Lodge. His interesting work has been read by every one and many have been convinced by his arguments. His great ability and the interesting nature of the subject, keep the reader spellbound; but when the impressions fade one realizes that he has to deal only with ingenuous explanations. I

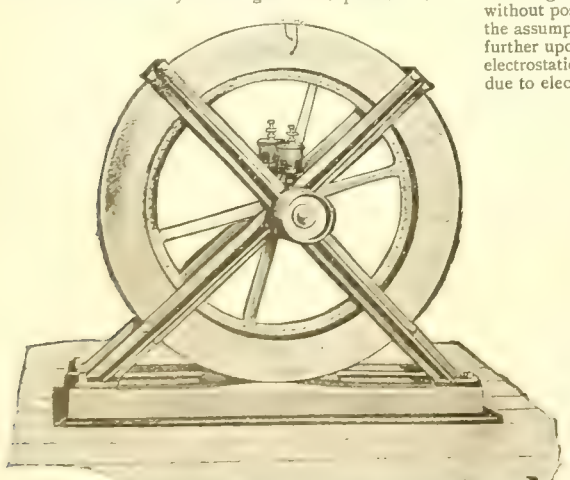

Fig. 2.—High Frequency Alternator with Revolving Disc Armature.

they range into hundreds of million millions per second. Nor can any one prove that there are transverse ether waves emitted from an alternate current machine, giving a small number of alternations per second; to such slow disturbances, the ether, if at rest, may behave as a true fluid. Electricity cannot be called ether in the broad sense of the term; but nothing would seem to stand in the way of calling electricity ether associated with matter, or bound ether; or, in other words, that the so called static charge of the molecule, is ether associated in some way with the molecule. Looking at it in that light, we would be justified in saying that electricity is concerned in all molecular actions.

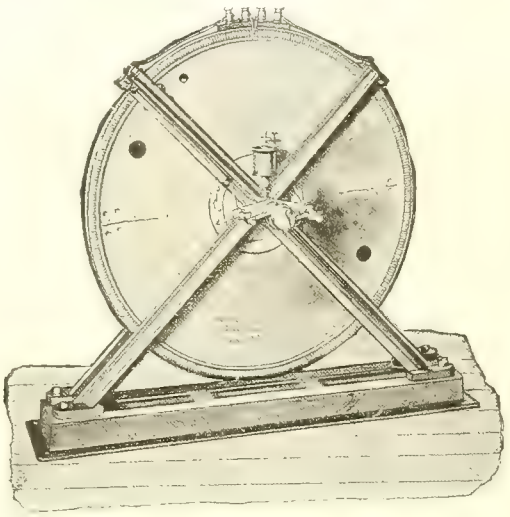

Fig. 1.—High Frequency Alternator with Drum Armature.

About fifteen years ago, Prof. Rowland demonstrated a most interesting and important fact, namely, that a static charge carried around produces the effects of an electric current. Leaving out of consideration the precise nature of the mechanism, which produces the attraction and repulsion of currents, and conceiving the electrostatically

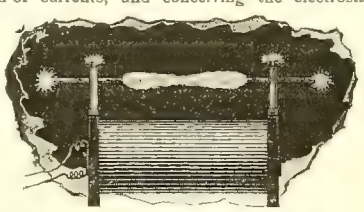

Fig. 6.—Streaming Discharge.

charged molecules in motion, this experimental fact gives us a fair idea of magnetism. We can conceive lines or tubes of force which physically exist, being formed of rows of directed moving molecules; we can see that these lines must be closed; that they must tend to shorten and expand, etc. It likewise explains in a reasonable way, the most puzzling phenomenon of all; permanent magnetism, and in general, has all the beauties of the ampere theory without possessing the vital defect of the same, namely, the assumption of molecular currents. Without enlarging further upon the subject, I would say, that I look upon all electrostatic, current and magnetic phenomena, as being due to electrostatic molecular forces.

Of all these phenomena the most important to study are the current phenomena, on account of the already extensive and ever growing use of currents for industrial purposes. It is now a century since thefirst practical source of current has been produced, and ever since, the phenomena which accompany the flow of currents, have been diligently studied, and through the untiring efforts of scientific men the simple laws which govern them have been discovered. But these laws were found to hold good only when the currents are of a steady character. When the currents are rapidly varying in strength quite different phenomena, often unexpected, present themselves and quite different laws hold good, which even now have not been determined as fully as desirable, though through the work principally of English scientists, enough knowledge has been gained on the subject to enable us to treat simple cases, which now present themselves in daily practice.

The phenomena which are peculiar to the changing character of the currents are greatly exalted when the rate of change is increased, hence the study of these currents is considerably facilitated by the employment of properly constructed apparatus. It was with this and other objects in view that I constructed alternate current machines capable of giving more than two million reversals of current per minute, and to this circumstance it is principally due that I am able to bring to your attention some of the results thus far reached, which I hope will prove to be a step in advance on account of their direct bearing upon one of the most important problems namely, the production of a practical and efficient source of light.

The study of such rapidly alternating currents is very interesting. Nearly every experiment discloses something new. Many results may, of course, be predicted, but many more are unforeseen. The experimenter makes many interesting observations. For instance, we take a piece of iron, and hold it against a magnet. Starting from low alternations and running up higher and higher we feel the impulses succeed each other faster and faster, get weaker and weaker, and finally disappear. We then observe a continuous pull; the pull, of course, is not continuous; it only appears so to us: our sense of touch is imperfect.

We may next establish an arc between the electrodes and observe as the alternations rise, that the note which accompanies alternating arcs gets shriller and shriller, gradually weakens and finally ceases. The air vibrations, of course continue, but they are too weak to be perceived; our sense of hearing fails us.

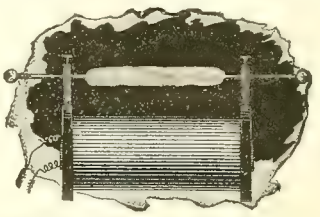

Fig. 5.—Flaming Discharge.

We observe the small physiological effects, the rapid heating of the iron cores and conductors, curious inductive effects, interesting condenser phenonema and still more interesting light phenomena, with a high tension induction coil. All these experiments and observations would be of the greatest interest to the student, but their description would lead me too far from the principal subject. Partly for this reason, and partly on account of the vastly greater importance, I will confine myself to the description of the light effects produced by these currents.

In the experiments to this end a high tension induction coil or equivalent apparatus for converting currents of comparatively low into currents of high tension, is used.

In general my experience tends to show that bodies which possess the highest specific inductive capacity, such as glass, afford a rather inferior insulation to others, which, while they are good insulators, have a much smaller specific inductive capacity, such as oils, for instance the dielectric losses being no doubt greater in the former. The difficulty of insulating, of course, only exists when the potentials are excessively high, for with potentials such as a few thousand volts there is no particular difficulty encountered in conveying currents from a machine giving, say 20,000 alternations per second to quite a distance. This number of alternations, however, is by far too small for many purposes, though quite sufficient for some practical applications. This difficulty of insulating is fortunately not a vital drawback; it affects mostly the size of the apparatus, for, when excessively high potentials would be used, the light-giving devices would be located not far from the apparatus, and often they would be quite close to it. As the air-bombardment of the insulated wire is dependent on condenser action, the loss may be reduced to a trifle by using excessively thin wires heavily insulated.

The investigator who desires to repeat the experiments which I will describe, with an alternate current machine, capable of supplying currents of the desired frequency and an induction coil, will do well to take the primary coil out and mount the secondary in such a manner as to be able to look through the tube upon which the secondary is

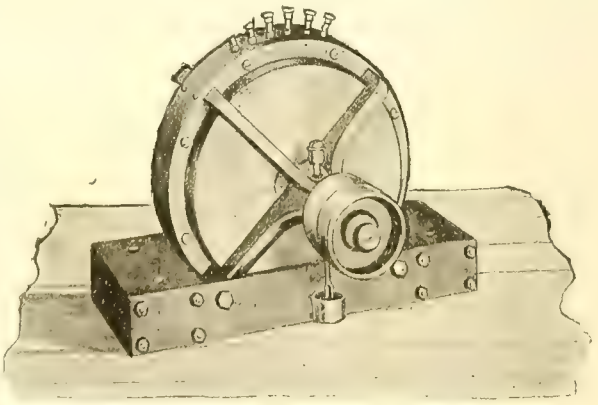

Fig. 3.—High Frequency Alternator with Stationary Disc Armature and Stationary Exciting Coil.

wound. He will then be able to observe the streams which pass from the primary to the insulating tube, and from their intensity he will know how far he can strain the coil. Without this precaution he is sure to injure the insulation. This arrangement permits, however, an easy exchange of the primaries, which is desirable in these experiments.

Fig. 1 represents the machine used in my experiments before the Institute. The field magnet consists of a ring of wrought iron with 384 pole projections. The armature comprises a steel disk to which is fastened a thin, carefully welded rim of wrought iron. Upon the rim are wound several layers of fine, well annealed iron wire, which, when wound, is passed through shellac. The armature wires

are wound around brass pins, wrapped with silk thread. The diameter of the armature wire in this type of machine should not be more than ⅛ of the thickness of the pole projections, else the local action will be considerable.

Fig. 2 represents a larger machine of a different type. The field magnet of this machine consists of two like parts which either inclose an exciting coil, or else are independently wound. Each part has 480 pole projections, the projections of one facing those of the other. The armature consists of a wheel of hard bronze, carrying the conductors which revolve between the projections of the field magnet. To wind the armature conductors, I have found it most convenient to proceed in the following manner: I construct a ring of hard bronze of the required size. This ring and the rim of the wheel are provided with the proper number of pins, and are both fastened upon a plate. The armature conductors being wound, the pins are cut off and the ends of the conductors are fastened by two rings which screw to the bronze ring and the rim of the wheel respectively. The whole may then be taken off and forms a solid structure. The conductors in such a type of machine should consist of sheet copper, the thickness of which of course, depends on the thickness of the whole projections; or else twisted thin wires should be employed.

Fig. 3 is a smaller machine, in many respects similar to the former, only here the armature conductors and the exciting coil are kept stationary, while only a block of wrought iron is revolved.

I deem it well to call the attention of the investigator to two things, the importance of which, though self-evident, he is nevertheless apt to underestimate; namely, to the local action in the conductors which must be carefully avoided, and to the clearance which must be small. I may add, that since it is desirable to use very high peripheral speeds, the armature should be of very large diameter in order to avoid impracticable belt speeds.

In operating an induction coil with very rapidly alternating currents, among the first luminous phenomena noticed are naturally those presented by the high tension discharge. As the number of alternations per second is increased, or as—the number being high—the current through the primary is varied, the discharge gradually changes in appearance. It would be difficult to describe the minor changes which occur and the conditions which bring them about, but one may note five distinct forms of the discharge.

First, one may observe a weak, sensitive discharge in the form of a thin, feeble-colored thread, Fig. 4. It always occurs when, the number of alternations per second being high, the current through the primary is very small.

When the current through the primary is increased the discharge gets broader and stronger, and the effect of the capacity of the coil becomes visible until, finally, under proper conditions, a white flaming arc, Fig. 5, often as thick as one's finger and striking across the whole coil, is produced. It develops remarkable heat, and may be further characterized by the absence of the high note which accompanies the less powerful discharges.

When the flaming discharge occurs the conditions are evidently such that the greatest current is made to flow through the circuit. This kind of discharge is the severest test for a coil; the break, when it occurs, is of the nature of that in an overcharged Leyden jar. To give a rough approximation I would state that, with an ordinary coil of, say 10,000 ohms' resistance, the most powerful arc would be produced with about 12,000 alternations per second.

When the frequency is increased beyond that rate the potential, of course, rises, but the striking distance, may nevertheless, diminish, paradoxical as it may seem. As the potential rises the coil attains more and more the properties of a static machine until finally, one may observe the beautiful phenomenon of the streaming discharge, Fig. 6, which may be produced across the whole length of the coil. At that stage streams begin to issue freely from all points and projections. These streams will also be seen to pass in abundance in the space between the primary and the insulating tube. When the potential is excessively high they will always appear, even if the frequency be low, and even if the primary be surrounded by as much as an inch of wax, hard rubber, glass or any other insulating substance.

Besides the potential, the intensity of the streams depends on the frequency; but if the coil be very large they show themselves, no matter how low the frequencies used. For instance, in a very large coil of resistance of 67,000 ohms, constructed by me some time ago, they appear with as low as 100 alternations per second and less, the insulation of the secondary being ¾ inch ebonite. When very intense they produce a noise similar to that produced by the charging of a Holtz machine, but much more powerful, and they emit a strong smell of ozone. The lower the frequency, the more apt they are to suddenly injure the coil. With excessively high frequencies they may pass freely without producing any other effect than to heat the insulation slowly and uniformly.

At the stage when the streaming discharge occurs, or with somewhat higher frequencies, one may, by approaching the terminals considerably and regulating properly the effect of capacity, produce a veritable spray of small silver-white sparks or a bunch of excessively thin silvery threads, Fig. 7, amidst a powerful brush—each spark or thread possibly corresponding to one alternation. This, when produced under proper conditions, is probably the most beautiful discharge, and when an air blast is directed against it, it presents a singular appearance.

If the frequency is still more increased, then the coil refuses to give any spark unless at comparatively small distances, and the fifth typical form of discharge may be observed, Fig. 8. The tendency to stream out and dissipate is then so great that when the brush is produced at one terminal no sparking occurs even if, as I have reepeatedly tried, the hand, or any conducting object, is held within the stream; and what is more singular, the luminous stream is not at all easily deflected by the approach of a conducting body.

At this stage the streams seemingly pass with the greatest freedom through considerable thicknesses of insulators, and it is particularly interesting to study their behavior. For this purpose it is convenient to connect to the terminals of the coil [illegible] spark instantly ceases and the discharge spreads into an intensely luminous circle several inches in diameter, provided the spheres are sufficiently large. The passage of the streams heats, and, after a while, softens the rubber so much that two plates may be made to stick together in this manner. If the spheres are so far apart that no spark occurs, even if they are far beyond the striking distance, by inserting a thick plate of glass the discharge is instantly induced to pass from the spheres to the glass in the form of luminous streams. It appears almost as though these streams pass *through* the dielectric. In reality this is not the case, as the streams are due to the molecules of the air which are violently agitated in the space between the oppositely charged surfaces of the spheres. When no dielectric other than air is present, the bombardment goes on, but is too weak to be visible; by inserting a dielectric the inductive effect is much increased, and besides the projected air molecules find an obstacle and the bombardment becomes so intense that the streams become luminous.

From the behavior of the dielectrics in these experiments we may conclude that the best insulator for these rapidly alternating currents would be the one possessing the smallest specific inductive capacity and at the same time one capable of withstanding the greatest differences of potential; and thus two diametrically opposite ways of securing the required insulation are indicated; namely, to use either a perfect vacuum or a gas under great pressure; but the former would be preferable. Unfortunately neither of these two ways is easily carried out in practice.

It is especially interesting to note the behavior of an excessively high vacuum in these experiments. If a test tube provided with external electrodes and exhausted to the highest possible degree be connected to the terminals of the coil, Fig. 10, the electrodes of the tube are instantly brought to a high temperature and the glass at each end of the tube is rendered intensely phosphorescent, but the middle appears comparatively dark, and for awhile remains cool.

When the frequency is so high that the discharge shown in Fig. 8 is observed, considerable dissipation no doubt occurs in the coil. Nevertheless, the coil may be worked for a long time, as the heating is gradual.

In spite of the fact that the difference of potential may be enormous, little is felt when the discharge is passed through the body, provided the hands are armed. This is to some extent due to the higher frequency, but principally to the fact that less energy is available externally, when the difference of potential reaches an enormous value, owing to the circumstance that with the rise of potential the energy absorbed in the coil increases as the square of the potential. Up to a certain point the energy available externally increases with the rise of potential, then it begins to fall off rapidly. Thus, with the ordinary high tension induction coil, the curious paradox exists, that, while with a given current through the primary the shock might be fatal, with many times that current it might be perfectly harmless, even if the frequency be the same. With high frequencies and excessively high potentials when the terminals are not connected to bodies of some size, practically all the energy supplied to the primary is taken up by the coil. There is no breaking through, no local injury, but all the material, insulating and conducting, is uniformly heated.

To avoid misunderstanding in regard to the physiological effect of alternating currents of very high frequency, I think it necessary to state that while it is an undeniable fact that they are incomparably less dangerous than currents of low frequencies, yet it should not be thought that they are altogether harmless. What has just been said is

COPYRIGHT. Not only the title, but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago Postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity, or any of its practical applications, is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—*the only general electrical paper published in the West*—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring Western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be promptly furnished on application.

The First Lord of the Admiralty, during his recent visit to this country, examined the coast defenses at New York. The [illegible] and some interesting tests showing the method of operation, were [illegible].

The question of [illegible] between lightships and lighthouses, which is attracting so much attention just now, is deserving of the best thought that [illegible].

reasonable cost has made it unprofitable to develop these regions, but now by utilizing water power for generating current, the cost of operation can be reduced to a minimum. The advantages to be derived from utilizing electricity in mining have already been shown. It is safe to say that rapid advances may be looked for in this field.

DETROIT is edeavoring to secure rapid transit and the street railway companies have expressed a willingness to extend their lines and substitute electricity in place of animal power, provided a twenty years' franchise is guaranteed. This is certainly a reasonable condition, and the citizens should gladly accept the proposition. To introduce a first class electric railway equipment, the Detroit companies will of course have to expend large sums of money, and their demand for a twenty years' franchise is only just.

THE completion of the electric railway lines in the Minneapolis-St. Paul system is hailed with delight by the people of both cities who desire to see a consolidation effected. Several years ago a proposition to unite these municipalities would be rejected, but now the scheme has many earnest advocates in both cities. The electric system has had much to do with bringing about this state of affairs. Owners of property between the cities desire to establish a better feeling, and as the electric railways connecting these cities afford excellent transportation facilities the property is valuable for residence purposes. Thus it is that one of the questions which have been the cause of much contention in the Northwest will probably be settled through the agency of the electric railroad.

THE electrical execution law has served to stir up the people of New York during the last week, and the daily papers throughout the country have been filled with accounts of the "last hours" of the condemned murderers in Sing Sing prison and the preparations for their execution. The idea of surrounding these executions with an air of mystery has had the effect of exciting the morbid curiosity and superstitious fears of the ignorant. The secrecy maintained has aroused the public mind to a sense of the danger attending the establishment of such a precedent. The fear that abuses might creep into the administration of justice under the cloak of secrecy and the fact that it would therefore be all the harder to correct these errors have done more toward creating opposition to the present law than the most sensational reports of bungled executions.

IT seems that the Order of Railway Telegraphers made a miscalculation in assuming that all it had to do was to knock at the doors of the Federation of Railway Employes to be admitted. A press dispatch from Terre Haute, Ind., states that the Supreme Council of the Federation rejected the application of the order—on what ground does not appear. The Brotherhood of Railway Station Men was likewise refused admission. It is further stated that representatives of the two unsuccessful organizations met at the Terre Haute hotel and formed an alliance, taking steps toward federation. A meeting will soon be held at which arrangements will probably be perfected for a second federation of railway employes. The Order of Railway Conductors is also at swords' points with the Federation, and, altogether, the latter aggregation appears to be in a bad way. We can only repeat our expression of regret that the railway telegraphers should have seen fit to mix in the melee.

A PERUSAL of Nikola Tesla's account of his recent experiments before the Institute leaves a different impression from that obtained through reading the incomplete reports of the lecture which have appeared heretofore. Most of the effects obtained, as was stated editorially last week, might have been deemed by some as only exaggerations of curious phenomena which are already familiar to many. The description, however, of the experiments prepared by the lecturer himself, carrying one as it does into the depths of a most interesting investigation of a fascinating subject, reveals that the experimenter has in reality opened up a line of work in which there are, apparently, unlimited possibilities. The boldness with which Mr. Tesla has struck out along a practically untrodden path cannot fail to excite admiration. As the reader follows him through these experiments there arises a feeling that the near future will witness astonishing developments in the direction of the application of currents of great frequency and high potential.

It is interesting to note that Mr. Tesla found during his [illegible] which possess [illegible] glass, afford a rather inferior insulation to others, which, while they are good insulators, have a much smaller specific inductive capacity. Or, to quote Mr. Tesla's own words relative to the behavior of the dielectrics in the experiments, "The best insulator for these rapidly alternating currents would be the one possessing the smallest specific inductive capacity and at the same time one capable of withstanding the greatest differences of potential." In the latter class, which includes oils, he considers the dielectric losses to be less than in the former.

He thus indicates two opposite ways of securing the necessary insulation, i. e., to use either a perfect vacuum or a gas under great pressure. The difficulty of employing either method, however, is appreciated.

Mr. Tesla's remarks in regard to the heating of iron cores in apparatus for rapidly alternating currents may be found to be of value to the transformer builder.

His reference to the ideal method of lighting and his experiment relative to it, are suggestive. Whether the future will see a practical application of the electrostatic field in a lighting system such as suggested by Mr. Tesla's experiments is another of the interesting points in which the paper abounds.

MINNEAPOLIS is contemplating the introduction of an extensive underground system of electric light wires. One of the local lighting companies will undertake the work, and as the management of the company seems desirous of giving the underground system a fair trial the result of the experiment, for such it must still be considered, will be awaited with considerable interest. Electric lighting companies generally do not look with favor on underground construction, and it has been charged that where they have introduced conduits which did not prove entirely satisfactory they permitted the failure for the purpose of forcing the authorities to abandon the hope of securing first-class service from underground work. In this case such a charge could not be considered by the bitterest opponent of electric lighting companies.

There are many problems connected with the operation of underground wires which must be solved before lighting companies can be induced to bury all their wires. The example of the Minneapolis company will do much toward establishing confidence in the mind of the public.

IN a recent number of the London *Electrical Review* attention is called to two communications from A. L. Stevenson and Wm. H. Massey, in which it is claimed that the application of electricity to mining has not progressed as rapidly in this country as American engineers assert. To any one familiar with the facts the absurdity of the statement is evident at a glance. Thus, Mr. Massey says: "I was in the United States for several weeks last autumn, and I utterly failed to find, except in one solitary case in a coal mine near Pittsburgh, a single practical application of electricity to any of the numerous purposes you mentioned." Of course Mr. Massey's "several weeks" in this country enabled him to visit all the principal mines in the Union and inspect the improved machinery and methods employed! Mr. Massey should realize, if he knows anything about America and its mining interests, that only a very general idea of what is being done here could be obtained in that time. There are mining camps in this country which alone would require more time for intelligent examination than Mr. Massey devoted to all the mining interests in the country combined.

Mr. Massey should know that there are several coal mines in Illinois where he might witness the "practical application of electricity" to coal cutting. Then again the same power is used for illuminating the mines, the operation of hoists and tramways and in numerous other applications, but possibly this is not "practical" enough for Mr. Massey! The manner in which Mr. Massey obtained his information is explained by him in this paragraph: "There was plenty of talk of what might be done in the near future, and I was shown, in various works, a few more or less promising experimental machines; but after discussing the whole question fully with well informed Americans, I came to the conclusion that the applications of electricity to mining work in England and Wales were far more numerous than those on the whole of the American continent put together." Further comment on Mr. Massey and his conclusions is unnecessary.

And now a word with Mr. Stevenson. After airing his opinions he says: "But American engineers still come over here and find much in our mines to learn, and I have not met with any who can meet me and prove that upon a single engineering question he is right, and I am wrong, in respect of either safety or economy."

In view of this admission it would be useless to endeavor to penetrate the density of this self-confessed ignorance.

[Continued from page 19.]

fers only to currents from an ordinary high tension induction coil, which currents are necessarily very small; if received directly from a machine or from a secondary of low resistance they produce more or less powerful effects and may cause serious injury, especially when used in conjunction with condensers.

From the nature of the phenomenon we can conclude that the higher the frequency the smaller must, of course, be the wind produced by the streams, and with sufficiently high frequencies no wind at all would be produced at the ordinary atmospheric pressures. With frequencies obtainable by means of a machine the mechanical effect is sufficiently great to revolve, with considerable speed, large pin-wheels, which in the dark present a beautiful appearance owing to the abundance of the streams, Fig. 11.

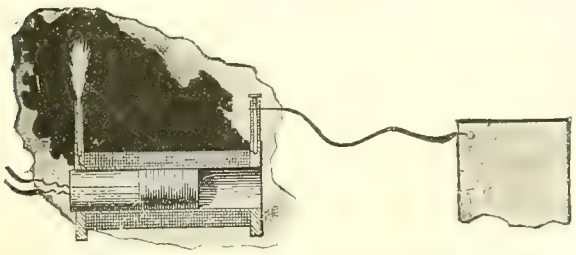

FIG 17A.—COIL ARRANGED FOR POWERFUL BRUSH EFFECTS.

In general, most of the experiments usually performed with a static machine can be performed with an induction coil when operated with very rapidly alternating currents. The effects produced, however, are much more striking, being of incomparably greater power. When a small length of ordinary cotton covered wire, Fig. 12, is attached to one terminal of the coil, the streams issuing from all points of the wire may be so intense as to produce a considerable light effect. When the potentials and frequencies are very high, a wire insulated with gutta percha or rubber and attached to one of the terminals appears to be covered with a luminous film. A very thin bare wire when attached to a terminal emits powerful streams and vibrates continually to and fro or spins in a circle, producing singular effect, Fig. 13.

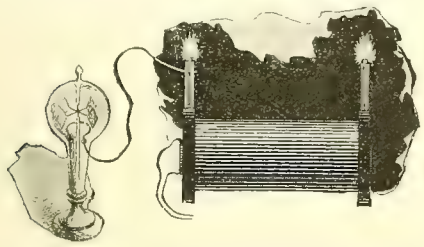

FIG. 19.—THE CROOKES EXPERIMENT ON OPEN CIRCUIT.

Another peculiarity of the rapidly alternating discharge of the induction coil is its radically different behavior with respect to points and rounded surfaces.

If a thick wire, provided with a ball at one end and with a point at the other, be attached to the positive terminal of a static machine, practically all the charge will be lost through the point, on account of the enormously greater tension dependent on the radius of curvature. But if such a wire is attached to one of the terminals of the induction coil it will be observed that with very high frequencies streams issue from the ball almost as copiously as from the point, Fig 14

FIG. 21.—LAMP WITH TWO FILAMENTS IN HIGHEST VACUUM WITH LEADING-IN WIRES.

There is still another and far more striking peculiarity of the brush discharge produced by very rapidly alternating currents. To observe this it is best to replace the usual terminals of the coil by two metal columns insulated with a good thickness of ebonite. It is also well to close all fissures and cracks with wax so that the brushes cannot form anywhere except at the tops of the columns. If the conditions are carefully adjusted—which, of course, must be left to the skill of the experimenter—so that the potential rises to an enormous value, one may produce two powerful brushes several inches long, nearly white at the roots which in the dark bear a striking resemblance to two flames of a gas escaping under pressure, Fig. 15. But they do not only [illegible], they are veritable flames for they are hot. Certainly they are not as hot as a gas burner but they would be so if the frequency and the potential would be sufficiently high. Produced with, say twenty thousand alternations per second, the heat is easily perceptible even if the potential is not excessively high. The heat developed is, of course, due to the impact of the air molecules, against the terminals and against each other. By preventing the change of the air molecules the local heating effect may be so exalted as to bring a body to incandescence. Thus, for instance, if a small button, or preferably a very thin wire or filament, be inclosed in an unexhausted globe and connected with the terminal of the coil, it may be rendered incandescent. The phenomenon is made much more interesting by the rapid spinning round in a circle of the top of a filament, thus presenting the appearance of a luminous funnel, Fig. 16, which widens when the potential is increased. When the potential is small the end of the filament may perform irregular motions, suddenly changing from one to the other, or it may describe an ellipse; but when the potential is very high it always spins in a circle, and so does generally a thin straight wire attached freely to the terminal of the coil.

One of the ways to prevent the streams between the primary and the tube, is to wind a short primary, Fig. 17 A, so that the difference of potential is not at that length great enough to cause the breaking forth of the streams through the insulating tubes. The length of the primary should be determined by experiment. Both the ends of the coil should be brought out on one end through a plug of insulating material fitting in the tube as illustrated. In such a disposition one terminal of the secondary is attached to a body the surface of which is determined with the greatest care so as to produce the greatest rise in the potential. At the other terminal a powerful brush appears which may be experimented upon

The above plan necessitates the employment of a primary of comparatively small size, and it is apt to heat when powerful effects are desirable for a certain length of time. In such a case it is better to employ a larger coil. Fig. 17 B, and introduce it from one side of the tube, until the streams begin to appear. In this case the nearest terminal of the secondary may be connected to the primary or to the ground, which is practically the same thing, if the primary is connected directly to the machine. In the case of ground connections it is well to determine experimentally the frequency which is best suited under the conditions of the test Another way of obviating the streams more or less, is to make the primary in sections and supply it from separate well insulated sources

FIG. 20.—LAMP WITH SINGLE BLOCK OF REFRACTORY MATERIAL.

In many of these experiments, when powerful effects are wanted for a short time it is advantageous to use iron cores with the primaries. In such case a very large primary coil may be wound and placed side by side with the secondary, and, the nearest terminal of the latter being connected to the primary, a laminated iron core is introduced through the primary into the secondary as far as the streams will permit.

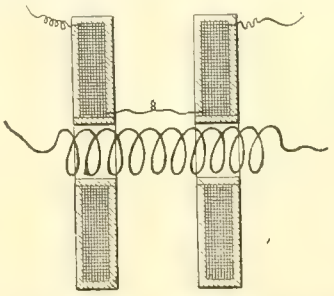

FIG. 18.—COIL FOR PRODUCING VERY HIGH DIFFERENCE OF POTENTIAL.

In these experiments if an iron core is used it should be carefully watched, as it is apt to get excessively hot in an incredibly short time. To give an idea of the rapidity of the heating, I will state, that by passing a powerful current through a coil with many turns, the inserting within the same of a thin iron wire for no more than one second's time is sufficient to heat the wire to something like 100° C.

But this rapid heating does not need to discourage us in the use of iron cores in connection with rapidly alternating currents. I have for a long time been convinced, that in the industrial distribution by means of transformers some such plan as the former might be practicable. We may use a comparatively small iron core, subdivided, or perhaps not even subdivided. We may surround this core with a

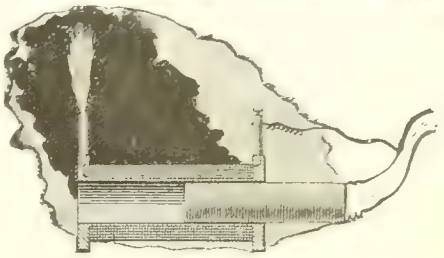

FIG. 17B.—COIL ARRANGED FOR POWERFUL BRUSH EFFECTS—ST ELMO'S HOT FIRE.

would be sufficiently thick only a limited amount of energy could be radiated in spite of the high temperature. Transformers have been constructed by me on that plan, but for lack of time, no thorough tests have as yet been made.

Another way of adapting the iron core to rapid alternations, or, generally speaking, reducing the frictional losses, is to produce by continuous magnetization a flow of something like seven thousand or eight thousand lines per square centimeter through the core and then work with weak magnetizing forces and preferably high frequencies around the point of greatest permeability.

FIG. 23.—LAMP WITH SINGLE STRAIGHT FILAMENT AND ONE LEADING-IN WIRE.

If it is desired to construct a coil for the express purpose of performing with it such experiments as I have described, or, generally, rendering it capable of withstanding the greatest possible difference of potential, then a construction as indicated in Fig. 18 will be found of advantage. The coil in this case is formed of two independent parts which are wound oppositely, the connection between both being made near the primary. The potential in the middle being zero, there is not much tendency to jump to the primary, and not much insulation is required. In some cases, the middle point may, however, be connected to the primary or to the ground. In such a coil the places of greatest difference of potential are far apart and the coil is capable of withstanding an enormous strain. The two parts may be movable so as to allow a slight adjustment of the capacity effect.

FIG. 22.—LAMP WITH TWO REFRACTORY BLOCKS IN HIGHEST VACUUM.

As to the manner of insulating the coil it will be found convenient to proceed in the following way: First the wire should be boiled in paraffine, until all the air is out; then the coil is wound by running the wire through melted

paraffine wetted for the purpose of fixing the wire. The coil is then taken off from the spool, immersed in a cylindrical vessel filled with pure melted wax and boiled for a long time until the bubbles cease to appear. The whole is then left to cool down thoroughly, and then the mass is taken out of the vessel and turned up in a lathe. A coil made in this manner and with care is capable of withstanding enormous potential differences.

It may be found convenient to immerse the coil in paraffine oil or some other kind of oil; it is a most effective way of insulating, principally on account of the perfect exclusion of air, but it may be found that after all a vessel

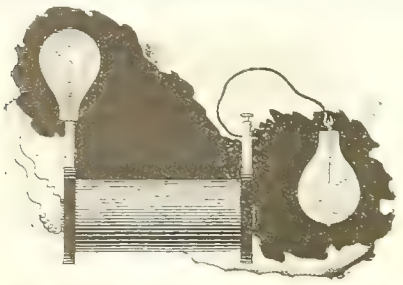

FIG. 24.—LAMPS WITH ONE LEADING-IN WIRE RENDERED INCANDESCENT.

filled with oil is not a very convenient thing to handle in a laboratory.

If an ordinary coil can be dismounted, the primary may be taken out of the tube and the latter plugged up on one end, filled with oil and the primary reinserted. This affords an excellent insulation, and prevents the formation of the streams.

I have stated that a body inclosed in an unexhausted bulb may be intensely heated by simply connecting it with a source of rapidly alternating potential. The heating in such a case, is in all probability, due mostly to the bombardment of the molecules of the gas contained in the bulb. When the bulb is exhausted the heating of the body is much more rapid and there is no difficulty whatever in bringing a wire or filament to any degree of incandescence by simply connecting it to one terminal of a coil of the proper dimensions. Thus, if the well-known apparatus of Prof. Crookes, consisting of a bent platinum wire with vanes mounted over it, Fig. 19, be connected to one terminal of the coil—either one or both ends of the platinum wire being connected—the wire is rendered almost instantly incandescent, and the mica vanes are rotated as though a current from a battery were used. A thin carbon filament, or, preferably, a button of some refractory material, Fig. 20, even if it be a comparatively poor conductor, inclosed in an exhausted globe, may be rendered highly incandescent; and in this manner a simple lamp capable of giving any desired candle power is provided.

The success of lamps of this kind would depend largely on the selection of the light-giving bodies contained within the bulb. Since, under the conditions described, refractory bodies—which are very poor conductors and capable of withstanding for a long time excessively high degrees of temperature—may be used, such illuminating devices may be rendered successful.

At the outset of this work the idea presented itself to

FIG. 26A.

FIG. 26B.

LAMP WITH ONE FILAMENT, ONE INSIDE AND ONE OUTSIDE CONDENSER COATING.

In an ordinary lamp this is impracticable on account of the destruction of the filament, and it has been determined by experience how far it is advisable to push the incandescence. It is impossible to tell how much higher efficiency could be obtained if the filament could withstand indefinitely, as the investigation to this end obviously cannot be carried beyond a certain stage; but there are reasons for believing that it would be very considerably higher. An improvement might be made in the ordinary lamp by employing a short and thick carbon; but then the leading-in wires would have to be thick, and besides, there are many other considerations which render such a modification highly impracticable. But in a lamp as above described, the leading-in wires may be very small, the incandescent refractory material may be in the shape of blocks offering a very small radiating surface, so that less energy would be required to keep them at the desired incandescence; and in addition to this the refractory material need not be carbon, but may be manufactured from mixtures of oxides, for instance, with carbon or other material, or may be selected from bodies which are practically non-conductors and capable of withstanding enormous degrees of temperature.

Various forms of lamps on the above described principle with the refractory bodies in the form of filaments, Fig. 21, or blocks, Fig. 22, have been constructed and operated by me, and investigations are being carried on in this line.

With these rapidly alternating potentials there is, however, no necessity of inclosing two blocks in a globe, but a single block, as in Fig. 20, or filament, Fig. 23, may be used. The potential in this case must of course be higher, but it is easily obtainable and besides it is not necessarily dangerous.

The facility with which the button or filament in such a lamp is brought to incandescence, other things being equal, depends on the size of the globe. If a perfect vacuum could be obtained, the size of the globe would not be of importance, for then the heating would be wholly due to the surging of the charges and all the energy would be given off to the surroundings by radiation. But this can never occur in practice. There is always some gas left in the globe and although the exhaustion may be carried to

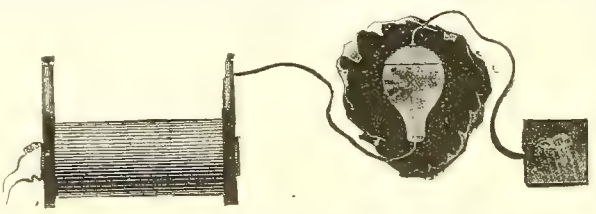

FIG. 29.—INCREASING THE BRILLIANCY OF LAMP ON ONE WIRE.

the highest degree, still the space inside of the bulb must be considered as conducting when such high potentials are used, and I assume, that in estimating the energy that may be given off from the filament to the surroundings we may consider the inside surface of the bulb as one coating of a condenser, the air and other objects surrounding the bulb forming the other coating. When the alternations are very low there is no doubt that a considerable portion of the energy is given off by the electrification of the surrounding air.

In order to study this subject better I carried on some experiments with excessively high potentials and low frequencies. I then observed that when the hand is approached to the bulb—the filament being connected with one terminal of the coil—a powerful vibration is felt being due to the attraction and repulsion of the molecules of the air which are electrified by induction through the glass. In some cases when the action is very intense I have been able to hear a sound, which must be due to the same cause.

When the alternations are low one is apt to get an excessively powerful shock from the bulb. In general, when one attaches bulbs or objects of some size to the terminals of the coil, one should look out for the rise of potential, for it may happen that by merely connecting a bulb or plate to the terminal, the potential may rise to many times its original value. When lamps are attached to the terminals, as illustrated in Fig. 24, then the capacity of the bulbs should be such as to give the maximum rise of potential under the existing conditions. In this manner one may obtain the required potential with fewer turns of wire.

The use of alternating currents of very high frequency makes it possible to transfer by electrostatic or electro-magnetic induction through the glass of a lamp, sufficient energy to keep a filament at incandescence, and so do away with the leading-in wires.

In the accompanying cuts some of the types of lamps of this kind are shown. Fig. 25 is such a lamp with a broken filament, and Fig. 26 A and 26 B one with a single outside and inside coating, and a single filament. I have also made lamps with two outside and inside coatings and a continuous loop connecting the latter.

The disruptive discharge of a condenser is especially suited for operating such lamps—with no outward electrical connections—by means of electromagnetic induction; the electromagnetic inductive effects being excessively high, and I have been able to produce the required incandescence with only a few short turns of wire. Incandescence may also be produced in this manner in a simple closed filament.

Leaving now out of consideration the practicability of such lamps, I would only say that they possess a beautiful and desirable feature, namely that they can be rendered, at will, more or less brilliant simply by altering the relative position of the outside and inside condenser coatings or inducing and induced circuits.

When a lamp is lighted by connecting it to one terminal only of the source this may be facilitated by providing the globe with an outside condenser coating, which serves at the same time as a reflector and connecting this to an insulated body of some size. Lamps of this kind are illustrated in Fig. 27 and Fig. 28. Fig. 29 shows the plan of connections. The brilliancy of the lamp may, in this case,

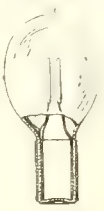

FIG. 25.—LAMP WITH TWO BLOCKS OR FILAMENTS AND A PAIR OF INDEPENDENT INSIDE AND OUTSIDE CONDENSER COATINGS.

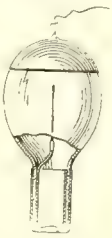

FIG. 28.—LAMP WITH ONE FILAMENT, ONE INSIDE AND ONE OUTSIDE CONDENSER COATING, AND AUXILIARY COATING.

be regulated within wide limits by varying the size of the insulated metal plate to which the coating is connected.

It is likewise practicable to light with one leading wire, lamps such as illustrated in Fig. 21 and Fig. 22, by connecting one terminal of the lamp to one terminal of the source and the other to an insulated body of the required size. In all cases the insulated body serves to give off the energy into the surrounding space, and is equivalent to a return wire. Obviously in the two last named cases, instead of connecting the wires to an insulated body, connections may be made to the ground.

During my investigations in this line, I endeavored to excite tubes, devoid of any electrodes, by electromagnetic induction, making the tube the secondary of the induction device, and passing through the primary the discharges of a Leyden jar. These tubes were made of many shapes, and I was able to obtain luminous effects which I then thought were due wholly to electromagnetic induction. But on carefully investigating the phenomena I found that the effects produced were more of an electrostatic nature. It may be attributed to this circumstance that this mode of exciting tubes is very wasteful, namely, the primary circuit being closed, the potential, and consequently the electrostatic inductive effect is much diminished.

When an induction coil, operated as above described, is used, there is no doubt that the tubes are excited by electrostatic induction and that electromagnetic induction has little, if anything, to do with the phenomena.

By placing a tube at some distance from the coil, and nearer to one terminal—preferably at a point on the axis of the coil—one may light it by touching the remote terminal with an insulated body of some size or with the hand, thereby raising the potential at that terminal nearer the tube. If the tube is shifted nearer to the coil so that it is lighted by the action of the nearer terminal, it may be made to go out by holding, on an insulated support, the end of a wire connected to the remote terminal, in the vicinity of the nearer terminal, by this means counteracting the action of the latter upon the tube. These effects are evidently electrostatic. Likewise, when a tube is placed

FIG. 27.—LAMP WITH ONE FILAMENT AND LEADING-IN WIRE AND EXTERNAL CONDENSER COATING.

at considerable distance from the coil, the observer may, standing upon an insulated support between coil and tube, light the latter by approaching the hand to it; or he may even render it luminous by simply stepping between it and the coil. This would be impossible with electromagnetic induction, for the body of the observer would act as a screen.

When the coil is energized by excessively weak currents, the experimenter may, by touching one terminal of the coil with the tube, extinguish the latter, and may again light it by bringing it out of contact with the terminal and allowing a small arc to form. This is clearly due to the respective lowering and raising of the potential at that terminal. In the above experiment when the tube is lighted through a small arc it may go out when the arc is broken, because the electrostatic inductive effect alone is too weak, though the potential may be much higher; but when

the arc is established the electrification of the end of the tube is much greater and it consequently lights.

If a tube is lighted by holding it near to the coil, and in the hand, which is remote, by grasping the tube anywhere with the other hand, the part between the hands is rendered dark and the singular effect of wiping out the light of the tube may be produced by passing the hand quickly along the tube and at the same time withdrawing

FIG. 33.—LAMP KEPT AT INCANDESCENCE ACROSS A THICK COPPER BAR—SHOWING NODES.

it slightly from the coil, judging properly the distance so that the tube remains dark afterward.

If the primary coil is placed sidewise as in Fig. 17 B, for instance, and an exhausted tube be introduced from the other side in the hollow space, the tube is lighted most intensely because of the increased condenser action, and in this position the striæ are most sharply defined. In all these experiments described and in many others the action s clearly electrostatic.

The effects of screening also indicate the electrostatic nature of the phenomena and show something of the nature of electrification through the air. For instance, if a tube be placed in the direction of the axis of the coil and an insulated metal plate be interposed, the tube will generally increase in brilliancy, or if it be too far from the coil to light, it may even be rendered luminous by interposing an insulated metal plate. The magnitude of the effects depends to some extent on the size of the plate. But if the metal plate be connected by a wire to the ground its interposition will always make the tube go out even if it be very near the coil. In general, the interposition of a body between the coil and tube increases or diminishes the brilliancy of the tube or its facility to light up, according to whether it increases or diminishes the electrification. When experimenting with an insulated plate the plate should not be taken too large else it will generally produce a weakening effect by reason of its great facility for giving off energy to the surroundings.

If a tube be lighted at some distance from the coil and a plate of hard rubber or other insulating substance be interposed, the tube may be made to go out. The interposition of the dielectric in this case only slightly increases the inductive effect, but diminishes considerably the electrification through the air.

In all the last described experiments tubes devoid of any electrodes may be used, and there is no difficulty in producing by their means sufficient light to read by. The light effect is, however, considerably increased by the use of phosphorescent bodies such as yttria, uranium glass, etc.

Instead of depending on induction at a distance to light the tube, the same may be provided with an external—and, if desired, also with an internal—condenser coating, and may then be suspended anywhere in the room from a conductor connected to one terminal of the coil, and in this manner a soft illumination may be provided.

The ideal way of lighting a hall or room would, however, be to produce such a condition in it that an illumina-

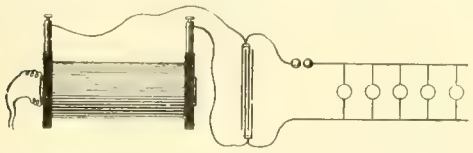

FIG. 31.—DIAGRAM OF CONNECTIONS FOR CONVERTING FROM HIGH TO LOW TENSION BY MEANS OF THE DISRUPTIVE DISCHARGE.

ting device could be moved and put anywhere, and that it is lighted, no matter where it is put and without being electrically connected to anything. I have been able to produce such a condition by creating in the room a powerful, rapidly alternating electrostatic field. For this purpose I suspend a sheet of metal a distance from the ceiling on insulating cords and connect it to one terminal of the induction coil, the other terminal being preferably connected to the ground. Or else I suspend two sheets as illustrated in Fig. 30, each sheet being connected with one of the terminals of the coil, and their size being carefully determined. An exhausted tube may then be carried in the hand anywhere between the sheets or placed anywhere, even a certain distance beyond them; it remains always luminous.

In such an electrostatic field interesting phenomena may be observed, especially if the alternations are kept low and the potentials excessively high. In addition to the luminous phenomena mentioned, one may observe that any insulated conductor gives sparks when the hand or another object is approached to it, and the sparks may often be powerful. When a large conducting object is fastened on an insulating support and the hand approached to it a vibration due to the rythmical motion of the air molecules is felt and luminous streams may be perceived when the hand is held near a pointed projection. When a telephone receiver is made to touch with one or both of its terminals an insulated conductor of some size, the telephone emits a loud sound; it also emits a sound when a length of wire is attached to one or both terminals, and with very powerful fields a sound may be perceived, even without any wire.

How far this principle is capable of practical application the future will tell. It might be thought that electrostatic effects are unsuited for such action at a distance. Electromagnetic inductive effects, if available for the production of light, might be thought better suited. It is true the electrostatic effects diminish nearly with the cube of the distance from the coil, whereas the electromagnetic inductive effects diminish simply with the distance. But when we establish an electrostatic field of force the condition is very different, for then instead of the differential effect of both the terminals we get their conjoint effect. Besides, I would call attention to the fact that in an alternating electrostatic field a conductor, such as an exhausted tube, for instance, tends to take up most of the energy, whereas in an electromagnetic alternating field the conductor tends to take up the least energy, the waves being reflected with but little loss. This is one reason why it is difficult to excite an exhausted tube at distance by electromagnetic induction. I have wound coils of very large diameter and of many turns of wire, and connected a Geissler tube to the ends of the coil with the object of exciting the tube at distance; but even with the powerful inductive effects producible by Leyden jar discharges the tube could not be excited unless at very small distance, although some judgment was used as to the dimensions of the coil. I have also found that even the most powerful Leyden jar

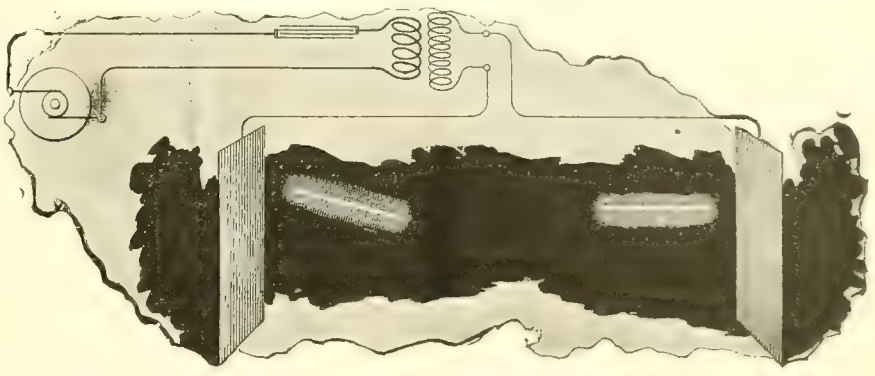

FIG. 30.—IDEAL METHOD OF LIGHTING A ROOM.—TUBES DEVOID OF ANY ELECTRODES RENDERED BRILLIANT IN AN ALTERNATING ELECTROSTATIC FIELD.

discharges are capable of exciting only feeble luminous effects in a closed exhausted tube, and even these effects upon thorough examination I have been forced to consider of an electrostatic nature.

When the terminals of a high tension induction coil, Fig. 31, are connected to a Leyden jar, and the latter is discharging disruptively into a circuit, we may look upon the arc playing between the knobs as being a source of alternating, or, generally speaking, undulating currents, and then we have to deal with the familiar system of a generator of such currents, a circuit connected to it, and a condenser bridging the circuit. The condenser in such case is a veritable transformer, and since the frequency is excessive, most any ratio in the strength of the currents in both the branches may be obtained. In reality the analogy is not quite complete for in the disruptive discharge we have most generally a fundamental instantaneous variation of comparatively low frequency and a superimposed harmonic vibration, and the laws governing the flow of currents are not the same for both.

In converting in this manner the ratio of conversion should not be too great, for the loss in the arc between the knobs increases with the square of the current, and if the jar be discharged through very thick and short conductors, with the view of obtaining a very rapid oscillation, a very considerable portion of the energy stored is lost. On the other hand, too small ratios are not practicable for many obvious reasons.

As the converted currents flow in a practically closed circuit the electrostatic effects are necessarily small, and I therefore convert them into currents or effects of the required character. I have effected such conversions in several ways. The preferred plan of connections is illustrated in Fig. 32. The manner of operating renders it easy to obtain by means of a small and inexpensive apparatus enormous differences of potential, which have been usually obtained by means of large and expensive coils. For this it is only necessary to take an ordinary small coil, adjust to it a condenser and discharging circuit forming the primary of an auxiliary small coil, and convert upward. As the inductive effect of the primary currents is excessively great the second coil need have comparatively but very few turns.

In Fig. 31 a plan of connections is shown for convert-

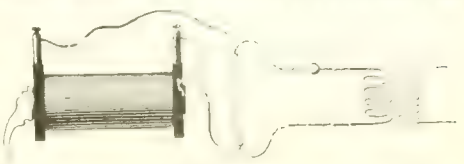

FIG. 32.—MANNER OF OPERATING AN INDUCTION COIL

erate ordinary lamps and even motors in this manner. The line being connected to the ground, all the wires could be handled with perfect impunity, no matter how high the potential at the terminals of the condenser. In these experiments a high tension induction coil, operated from a battery or from an alternate current machine, was employed to charge the condenser; but the induction coil might be replaced by an apparatus of a different kind, capable of giving electricity of such high tension. In this manner direct or alternating currents may be converted, and in both cases the current impulses may be of any desired frequency. When the currents charging the condenser are of the same direction, and it is desired that the converted currents should also be of one direction, the resistance of the discharging circuit should, of course, be so chosen that there are no oscillations.

In operating devices on the above plan I have observed curious phenomena of impedance which are of interest. For instance, if a thick copper bar be bent as indicated in Fig. 33 and shunted by ordinary incandescent lamps, then, by passing the discharge between the knobs, the lamps may be brought to incandescence although they are short-circuited. When a large induction coil is employed it is easy to obtain nodes on the bar, which are rendered evident by the different degrees of brilliancy of the lamps, as shown roughly in Fig 33. The nodes are never clearly pronounced, but there are simply maxima and minima of potential along the bar. This is probably due to the irregularity of the arc between the knobs. In general, when the above described plan of conversion from high to low tension is used, the behavior of the disruptive discharge may be closely studied. The nodes may also be investigated by means of an ordinary Cardew voltmeter, which should be well insulated. Geissler tubes may also be lighted across the points of the bent bar; in this case, of course, it is better to employ smaller capacities. I have found it practicable to light up in this manner a lamp and even a Geissler tube shunted by a short heavy block of metal, and this result seems at first very curious. In fact, the thicker the copper bar in Fig. 33, the better it is for the success of the experiments, as they appear more striking. When lamps with long slender filaments are used it will

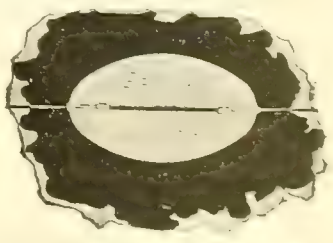

FIG. 34.—PHENOMENON OF IMPEDANCE IN AN INCANDESCENT LAMP.

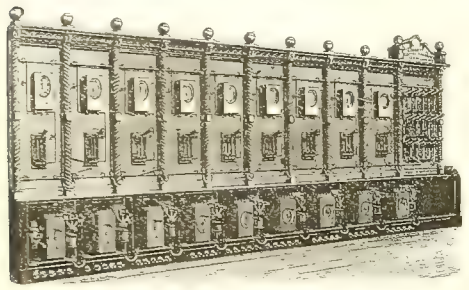
be often noted that the filaments are from time to time violently vibrated, the vibration being smallest on the nodal points. This vibration seems to be due to an electrostatic action between the filament and the glass of the bulb.

In some of the above experiments it is preferable to use special lamps having a straight filament, as shown in Fig. 34. When such a lamp is used a still more curious phenomenon than those described may be observed. The lamp may be placed across the copper bar and lighted up by using somewhat larger capacities, or, in other words, smaller frequencies or smaller impulsive impedances, the

filament may be brought to any desired degree of incandescence. But when the impedance is increased, a point is reached when comparatively little current passes through the carbon and most of it through the rarefied gas, or perhaps it may be more correct to state that the current divides nearly evenly through both, in spite of the enormous difference in the resistance, and this would be true unless the gas and the filament behave differently. It is then noted that the whole bulb is brilliantly illuminated, and the ends of the leading in wires become incandescent and often throw off sparks in consequence of the violent bombardment; but the carbon filament remains dark. This is illustrated in Fig. 34. Instead of the filament a single wire extending through the whole bulb may be used, and in this case the phenomenon would seem to be still more interesting.

From the above experiment it will be evident, that when ordinary lamps are operated by the converted currents, those should be preferably taken in which the platinum wires are far apart, and the frequencies used should not be too great, else the discharge will occur at the ends of the filament or in the base of the lamp between the leading in wires, and the lamp might then be damaged.



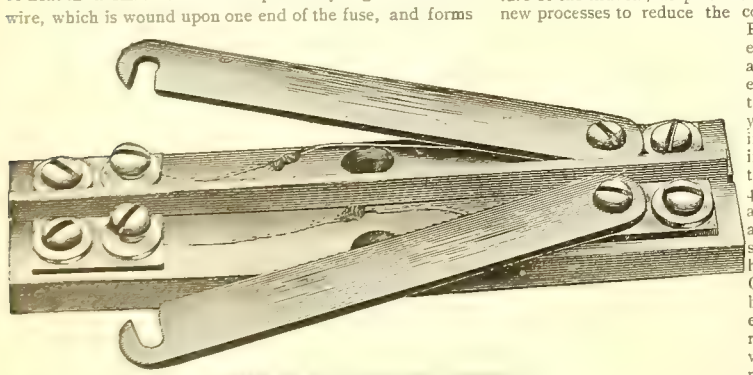
SWITCH-BOARD FOR THE ROCHESTER ELECTRIC RAILWAY.

Switch-board for the Rochester Electric Railway.

In the accompanying cut is shown a switch-board for the electric railway at Rochester, N. Y. The upper portion is built of mahogany, delicate workmanship being shown in the pillars and cornices. The rheostats and protecting devices and heavy switches are arranged in a row on the lower portion of the board, which is made of slate highly polished and given an ebony finish. The upper portion of the board is occupied by regulating devices and switches. The board, which was made by the Short Electric Railway company of Cleveland, is pronounced the most complete in the country. The cut is reproduced from the *Street Railway Journal*.

The W. B. G. Circuit Protector.

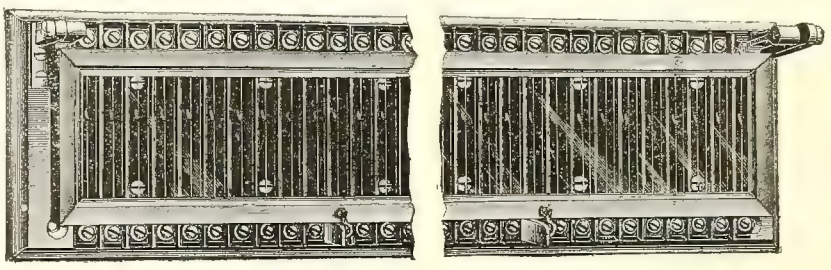
It is well known that a piece of fine wire laid out straight and exposed to the air can easily carry enough current to destroy a pair of magnet coils composed of much larger wire than the straight piece, and it is upon this fact that the construction of the device illustrated in the cuts is based. The main features of the "W. B. G." protector is the manner in which the fuse is melted by the generation of heat in a small coil of comparatively high resistance wire, which is wound upon one end of the fuse, and forms



2-WIRE W. B. G. CIRCUIT PROTECTOR.

Proposed Consolidation of Supply Interests.

The project of consolidating the electrical supply houses of the country has been revived by the recent failure of the Empire City Electric company. The sharp competition and tight money market had made it impossible to continue the business, and the promoters of the enterprise endeavored to effect a combination, but failed. Several attempts were made, it is asserted, to form a trust of the leading supply companies of the country, but without success. F. S. Terry of the Electrical Supply company, Chicago, speaking of the failure, says: "It is not surprising that the promoters of the company should desire to discontinue a business which has grown unprofitable. The supply companies are in the midst of a dull season, and the profits are very much narrowed by the bitter competition between the numerous companies. There have been frequent attempts toward the formation of a trust here but none has succeeded as yet, nor are they likely to succeed in the future." He added: "However there are plans on foot at present for an arrangement between the companies to regulate prices, and the prospects for their success are encouraging. Until this is done the dealer in electrical supplies must be satisfied with a narrow margin of profits."



50-WIRE W. B. G. CIRCUIT PROTECTOR BOARD.

La Boiteaux Fan Outfit.

In the accompanying illustration is shown a new style of fan motor brought out by the La Boiteaux Electric Motor & Fan company of Cincinnati. The distinguishing feature is the revolution of the whole outfit—motor, fan and all—on the iron pedestal which serves as the base. While the fan itself is whirling around at the rate of 2 000 revolutions per minute the whole apparatus slowly revolves on the upright pedestal at the rate of ten revolutions per minute. It is claimed that this double motion results in greater effectiveness in stirring the air, while the unpleasant effects of a continuous draught in one direction are not felt. The fans are furnished with or without lamp attachments.

Production of Aluminum.

The statistics gathered by the census department of the government relating to the production of aluminum will be received with special interest by the electrical fraternity. A bulletin relating to this metal has been prepared by R. L. Packard of the Division of Mines and Mining of the Census Office. This interesting metal has at last reached the stage of actual production, and the United States is now one of the leading producers. The all-important feature of the industry at present, however, is the effort by new processes to reduce the cost of making the metal Prominence is therefore given to a concise and very exact resume of the methods of extraction of aluminum and their results for a number of years, with other valuable information relating to this industry. The product for the census year 1889 was 47,468 pounds, including aluminum in alloys, valued at $97,335. The principal sources of aluminum have heretofore been cryolite from Greenland and imported bauxite, but recent discoveries of bauxite have been made in Arkansas, which will, no doubt, lead to the more extensive use of the domestic article.

Mr. Packard believes that aluminum has been attracting an amount of attention during the last two or three years which is out of proportion to its actual importance as a metal and the position in the arts which it has hitherto occupied. This is accounted for, he says, by the comparatively recent appearance of the metal in commerce, the difficulty of extracting it, and the unfamiliar and elaborate metallurgical processes which have been invented in consequence. Some of these processes are reproductions on a large scale of experiments which are not ordinarily used, even in chemical laboratories. A brief resume of the history of these methods of extraction and their results will give a correct idea of the scope and merit of the industry.

In 1807 and 1808 Sir Humphrey Davy succeeded in obtaining the metals from the alkaline earths, baryta, strontia, lime, and magnesia, by electricity. His method was to place a piece of the respective earths, on a strip of platinum connected with the positive pole of a powerful battery, put mercury in a small cavity in the paste, and connect it with the negative wire of the battery. Under the influence of the current the metallic oxide (the earth) was decomposed, an amalgam of the metal which it contained was formed, and the pure metal was obtained from this by distilling off the mercury. On applying this method to a paste made of alumina, Sir Humphrey Davy could not obtain the expected amalgam; he therefore varied the experiment in a way which is notable in view of certain recent methods, and which he described as follows:

"The first experiment by which I obtained evidence of its composition was made in 1808 by fusing iron negatively electrified in contact with it. The earth was moist in this process, and a very high voltaic power was applied. The globule of metal obtained was whiter than pure iron, effervesced slowly in water, becoming covered with a white powder, and the solution in muriatic acid decomposed by an alkali afforded alumina and oxide of iron."

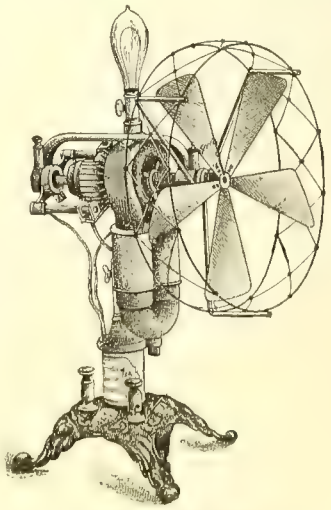
He continues:

"By passing potassium in vapor through alumina heated to whiteness the greatest part of the potassium became converted into potassa, which formed a coherent mass with that part of the alumina not decompounded, and in this mass there were numerous gray particles, having the metallic luster and which became white when heated in the air, and which slowly effervesced in water."—1840, *vol.* 4, *p.* 262,

Inconclusive as these experiments are as far as the separation of aluminum is concerned, they are interesting as the pioneers of the two lines of experiments, the electrical and chemical, each of which afterward led to the establishment of a commercial process.

The next step in advance was in the line of chemical experiment. Sir Humphrey Davy had failed to obtain aluminum from alumina, the oxide of the metal, by potassium vapor. Some twenty years later Woehler, by substituting the chloride of aluminum for the oxide in this operation, succeeded in obtaining the metal, and was able to determine its physical properties.

In the account of his own works, published in 1827,[1] Woehler describes Oersted's experiments, made three years previously, and attributes to him the discovery of volatile aluminum chloride, which he prepared by the method, now well known in practice, of passing chlorine gas over a mixture of alumina and carbon heated to redness. By acting on the chloride so obtained with potassium amalgam Oersted stated that he had obtained an amalgam of aluminum from which he had recovered the metal by distilling off the mercury. Woehler repeated this experiment, but was unable to obtain aluminum, the metal remaining, after distilling off the mercury, being only potassium left over from the amalgam which had been used in the experiment. He did, however, succeed in reducing aluminum chloride by potassium itself, operating in porcelain crucibles. The aluminum was obtained in the form of a gray powder, and was not pure.



LA BOITEAUX FAN OUTFIT.

In 1845 Woehler renewed his experiments,[2] but in order to avoid the lively chemical reaction he varied the arrangement in such a way as to keep the aluminum chloride and potassium separate while the potassium was melted in the vapor of the chloride. This was accomplished in two ways: First, he introduced the chloride into a platinum tube, and then placed a platinum boat containing potassium in the tube near it. The tube was gradually heated to redness, when the chloride was volatilized and passed in vapor over the melted potassium, which decomposed the chloride and liberated the aluminum. He also placed the

1. Poggendorff's Annalen, xi, p. 117.
2. Poggendorff's Annalen, lxiv, 1845, pp. 147-451

potassium in a small porcelain crucible, which was set in a larger one, and the space between was filled with chloride. The whole was well covered and heated, when the reaction occurred. As before, the aluminum so obtained seemed to be in the form of a gray powder, but on closer inspection this powder was seen to be composed of tin-white metallic globules. Woehler determined the specific gravity and other properties of these globules.

These laboratory experiments were resumed by H. Sainte-Claire Deville in France in 1854, who substituted sodium for potassium and operated on a larger scale than his predecessors He placed aluminum chloride in considerable quantity in a glass tube, into which porcelain boats containing sodium were introduced, and the tube was then heated. The aluminum chloride was volatilized, and, coming in contact with the melted sodium, was decomposed thereby with a lively incandescence, forming chlorides of aluminum and sodium and setting free the aluminum, which was retained in the double chloride in a finely divided state. This mixture was then placed in boats made of retort carbon, which were highly heated in a porcelain tube, through which a current of dry hydrogen was passed. The double chloride was distilled off by this means, leaving the aluminum, which was afterward re melted and run into ingots. This was the method which Deville carried out on a large scale in 1855 in a furnace consisting of a retort for distilling the aluminum chloride, a chamber connected therewith containing iron nails to hold any ferric chloride which might distill over, and a third chamber beyond this containing trays of sodium. The inventor found much to improve in the details of the process, and by 1859 it had become modified so that the reduction was effected in a reverberatory furnace and fluorspar or cryolite was used as a flux. The double chloride aluminum and sodium which was used in this operation was made by heating a mixture of alumina, carbon, and common salt in a retort and passing dry chlorine gas through it, on the principle introduced by Oersted, whereby the double chloride was distilled over and caught in a receiver. Since that date many improvements have been made in the way of lessening the cost of the materials used in the process, especially in the manufacture of sodium by the Castner process in England, but the metallurgy remains substantially as it was when Deville established it.[1]

This was the only process in practical operation in Europe down to three or four years ago. No serious attempt was ever made to introduce it into this country, because the limited uses and the high price of aluminum and its difficult metallurgy, which would be still more costly in this country than in Europe, where the refinements of chemical technology are more familiar than here, all conspired to repel investment in any large way.

The first step in advance in the electro-metallurgy of aluminum dates from the electrical decomposition of the fused double chloride of aluminum and sodium in 1854. The electrical decomposition of fused magnesium chloride by Prof. Bunsen led to operating in a similar way on the fused double chloride of aluminum and sodium. Bunsen, in Germany, and Deville, in France, obtained metallic aluminum in this way, but no attempt was made to repeat the operation on an industrial scale until a much later date, when the introduction of modern dynamo electric machines made it feasible.

The Siemens electric furnace, patented in England in 1879 which was the forerunner of certain recent furnaces, may be regarded as a further advance toward the electric-metallurgy of aluminum. It consisted of a large crucible, placed in a vessel filled with charcoal as a non-conductor. The cathode passed through the bottom of the crucible, and was in contact with the metal to be melted by the heat of the arc. The anode passed through a hole in the cover of the crucible, and the distance between the poles was ingeniously regulated by a solenoid. [2] Iron. steel, and platinum were melted in this crucible.

The intense heat which the electric current is capable of producing for metallurgical purposes was now known. It was also known that aluminum could be obtained by electrolysis, and the time was ripe for the industrial application of these facts as soon as dynamo electricity would be made available. Accordingly, in the last decade electro-metallurgical processes for obtaining aluminum have become favorite subjects for patents with inventors. It is sufficient to describe briefly the two which have been commercially successful in this country, and they will serve as types of all. The earlier of these, the Cowles process, was established in 1885, and is at present confined to the production of aluminum alloys, viz., aluminum bronze (and brass) and ferro aluminum. This process, which is now well known to persons interested in metallurgy, consists in passing the current from a powerful dynamo through a mixture of alumina (in the form of corundum, bauxite, etc.), carbon, and pieces of copper contained in a suitable vessel lined with carbon, through the ends of which vessel the large terminals of the dynamo are inserted. The mixture is arranged so as to prevent short circuiting. On passing the current the alumina is reduced in the presence of carbon and unites with the melted copper to form an alloy rich in aluminum This alloy is afterward remelted, and enough copper added to it to reduce the aluminum contents to the proportions desired for aluminum alloys of the required grades.

The production of aluminum bronze has been increased since 1885 from 4,000 to 5,000 pounds valued at $1,600 to $2,000 to 144,764 pounds valued at $57,000 in 1887. It is now much greater.

Besides aluminum bronze the Cowles company makes ferro aluminum by the same process by which the bronze is made, substituting iron for copper. The alloy, containing from 5 to 10 per cent. of aluminum, is used as a vehicle for introducing aluminum into molten iron to increase its tensile strength and solidity. An idea of the growing demand for ferro aluminum for this metallurgical use is obtained from the statement of the Cowles company that they made in 1886 from 2,000 to 3,000 pounds, valued at from $780 to $1,170, and in 1887, 42,617 pounds, valued at $16,621. The total aluminum alloys produced in 1887 was 171,759 pounds.

Many proposals have been made and many patents obtained for making alloys of aluminum with iron and sometimes with copper by reducing alumina with carbon in the presence of fluxes and the metals. Clay, kaolin, and other compounds of alumina, it is asserted, may be used for this purpose. Sometimes the iron or copper is added to the melted mixture used as a "bath," sometimes the mixture is added as a flux to iron in a cupola or similar furnace, and sometimes it is used as a paste on iron, which is then heated. The object in most cases is to make an iron aluminum alloy for "beneficiating" iron. The announcement of the good effect produced on iron by adding minute quantities of aluminum to it while melted and Mr. Keep's experiments on this subject have probably led inventors to patent processes of the above kind. It is to be regretted that these processes do not yet offer clear and certain evidence that they are distinct and decided improvements like the electrical processes, or, indeed, that they are operative in the manner described.

The extraction of aluminum itself is also effected by dynamo electricity, and is a new industry carried on under the patents of C. M. Hall. The process consists in forming a fused bath of the fluorides of aluminum, calcium, and sodium, to which calcium chloride is subsequently added, by melting a mixture of cryolite, aluminum fluoride, and fluorspar in a suitable vessel lined with carbon, adding alumina thereto, and then separating the aluminum by the current from a dynamo, the carbon electrodes of which dip into the bath. The process is continuous, because the alumina is renewed as it becomes exhausted. One merit of the process is that the fused bath is of less specific gravity than the aluminum set free, which therefore sinks to the bottom of the vessel. If alloys are desired, the negative electrode is formed of the metal which it is desired to alloy with aluminum. Variations in the composition of the bath are described in the different patent specifications, but that above given is believed to be the one used in practice. The total production of aluminum in the United States during 1889, including that contained in alloys, was 47,468 pounds, with a total value of $97,335.

Until the recent metallurgical use of aluminum in treating molten iron was introduced the metal was worked in this country in a small way, principally for parts of optical, engineering, and astronomical instruments, balance beams, light weights, and the like, where lightness and strength are desired. An idea of the extent of its use may be had from the fact that the amount imported into this country in one year was valued at $14,086

France was the only country which produced aluminum commercially until a few years ago. It had never been seen in any quantity until the Paris Exposition of 1855, where it was shown in ingots and in the form of manufactured articles of various kinds. Among ornamental articles it was noticed that a small body of the imperial guard wore breastplates of aluminum. The price of the metal was then 2,000 francs a kilo.

Aluminum was still somewhat of a curiosity in 1878, and was exhibited at the Paris Exposition in blocks, wire, sheets, and foil, and according to the report of the United States commissioners in the form of "objects, from a thimble and penholder to dinner sets of aluminum bronze and metal." Telescopes, opera glasses, and other optical instruments, mounted wholly or in part in aluminum, and chemical balances made of the same metal, were shown, which were very light and strong.

There was an English manufacture of aluminum from about 1860 to 1874, but no statistics of its production are obtainable. It could not have been very considerable, as the price of the metal was then very high. The Castner process was inaugurated in England in 1888. Supposing 5,000 pounds per annum to represent the English production from 1883, when the Webster process was put in operation, to 1888, we have 30,000 pounds, which, with the 12,000 pounds for 1889, equaling 42,000 pounds, or 21 tons, may be regarded as the English production up to the beginning of 1890. The French and English production together would therefore amount to about 82 tons. The Aluminum and Magnesium Fabrik, at Hemelingen, near Bremen, has been in operation since the latter part of 1887, and has supplied all the aluminum produced in Germany.

The tenacity of commercial aluminum is given by W. J. Keep as 18,866 pounds per square inch for a specimen, the probable composition of which was aluminum, 96.96 per cent.; silicon, 0.59 per cent., and iron, 1.79 per cent. This was an average of four tests which were made by Theodore Stevens. The specific gravity of the metal was 2.66. Another series of tests of commercial aluminum containing 95.50 per cent. aluminum, 1 62 per cent. silicon, and 2.88 per cent. iron gave 17,425 pounds per square inch tensile strength, the specific gravity being 2.72.[1] On the other hand, tests made by W. H. Barlow give 26,800 pounds per square inch as the tensile strength, and tests of aluminum made by the Deville-Castner process give from 25,000 to 30,000 pounds.[2]

The principal sources of aluminum have hitherto been cryolite from Greenland and imported bauxite. The Greenland mine is at Evigtok near Arksut. Before 1860 only small quantities of this cryolite were exported, but soon after that date the deposit was systematically worked, and cryolite was exported in considerable quantities. In recent years an American company, the Pennsylvania Salt Manufacturing company, has imported several thousand tons annually. A writer in the New York *Sun* described the appearance of the mine or quarry as "a hole in the ground, elliptical in shape, and, say, 450 feet long by 150 wide." The pit is 100 feet deep, and drills have penetrated [illegible] This prospecting promises well for the future. The mine [illegible] and load directly from the "stock pile" of the mine.

The increased demand for alumina bearing materials has [illegible] in 1887, at which time the deposit had not been opened to any extent, was published by Edward Nichols in the Transactions of the American Institute of Mining Engineers, volume 16 (1888), page 905.

The most recent discoveries of bauxite are in Saline and Pulaski counties, Arkansas. Dr. J. C. Branner, the State geologist, has made a report on the subject to the governor of that state, from which the following information is condensed.

The mineral or ore occurs in Arkansas only in tertiary areas and in the neighborhood of granites. It appears in irregular deposits, whose thickness and extent are determinable only by direct methods of examination. The Arkansas bauxite beds are known to cover a total area of about 640 acres in Saline and Pulaski counties.

"Alum beds" have been found in Purgatory valley, about twelve miles east of Trinidad, Colo., and some assessment work has been done there in locating claims and opening up the deposits. Two deposits of a similar material have also been found on the Gila river, in New Mexico, one of which is some twenty miles from Silver City. It is said to be extensive, and many claims have been taken up and some prospecting work done. The other deposit is on the southern Gila, and fluorspar has been found in the neighborhood.

CORRESPONDENCE.

New York Notes.

NEW YORK, July 4.—The question of lightning protectors has lately been under discussion in various metropolitan journals. The present discussion arose partly from the paper recently read before the Institute of Electrical Engineers by Mr. Hodges, when he drew attention to his "patent lightning dispeller," and partly from the efforts of one of the leading daily papers to draw forth opinions from electrical men on the action of lightning and lightning rods generally. The consensus of opinion is against Mr. Hodges' theory and his practice and his "dispeller." Mr. Hodges claims to have found no case where metal has been "dissipated," and damage has been done in the immediate neighborhood of the metal. Others, however, cite just such cases as Mr. Hodges failed to discover in his search of the "records." To all arguments against the probable efficacy of his scheme of protection Mr. Hodges replies immovably, that he has stated a physical law; and laws are serious things to trifle with, especially physical laws. The other day during a heavy thunderstorm in New Jersey two horses drawing a private carriage were killed by lightning. One would think there ought to be enough dissipatable metal on harness to protect a horse, but the records do not say in this case whether any of it was dissipated; regarding the destruction of the horses there was no doubt. Curiously enough, Mr. Hodges does not bring forward a single case where his "dispeller" has dissipated and dispelled, but he goes on advertising his "system" with the utmost confidence. Some people may think that five dollars is a pretty good price to pay for 75 feet of copper tape, especially as the tape must all be dissipated in a single flash if it does its work properly. In some parts of the country protection from lightning would come pretty dear at five dollars a flash.

The Rapid Transit Commissioners are engaged in considering plans for an east side road, and they find considerable difficulty in selecting a route above the Harlem River. A public hearing was given the other day to representatives of associations in the annexed district and there was considerable difference of opinion as to the route which should be chosen; the district to be served is a large and scattered one and each section wants the road to run through or near it. There is considerable dissatisfaction expressed at the dilatoriness of the Commission in arriving at a decision, and its action in the case of the west side road has really received far more praise than it deserved. The route chosen was obviously the only one to choose and an underground road worked by electric motors was a foregone conclusion long before the decision was announced. The report of the Commission was studiously vague and indefinite in every other respect, and every promoter of a system claimed that his was the system recommended in the report. The Commission ignominiously shirked the responsibility of reporting on the various plans submitted for the construction and equipment of the road, leaving the engineers to make their choice. The real work only begins when the commission has made its weak kneed report, and one cannot but think how much better it would have been to appoint a commission of engineers at first leaving the respectable business men to look after their business. It is pretty obvious that the Commission is by no means able to handle the really gigantic task allotted to it, and it is

"distinctly disappointing to experience such long delays with so little result.

Carping spirits continue to carp at the idea of an electric underground road, although the *Sun*, chief among carpers, has maintained a discreet silence since the publication of Mr. Sprague's challenge. A carper with a decidedly original turn of mind wrote to an evening paper to suggest that the reason why the traffic on the City and South London line is so small is to be found in the disinclination of the public [illegible]. (The italics are the carper's). He suggests that the New York public will feel the same way and says that capital will hesitate to come forward if there is any reason to suppose that [illegible]. As a matter of fact, the City and South London road carries all the passengers it can possibly accommodate, and the profits on the first six months' working amounted to about $100,000. The road is a short one and serves a comparatively unimportant district of London, which previously was dependent entirely on omnibuses, so that naturally the number of passengers carried is not large, compared, say, with the number carried by one of the New York elevated roads. The elevators are considered a distinct boon and are very freely used, as of course they always would be wherever they save time and trouble. The objection is too grotesque for serious discussion, but it serves to show what trivialities carping spirits will indulge in.

Attention is being drawn here to the movement now on foot in England to establish telegraphic communication between lightships and lighthouses both on the mainland and on adjacent islands, and the general telegraph system. It is urged that steps should be taken to place the lighthouses and lightships on the Atlantic coast in communication with the mainland, and it is thought that the shipping interests will be willing to help in paying the expense of a work so obviously to their advantage. The harbor master of Bridgeport, Conn., points out that the system of signaling on Long Island Sound is good in fair weather only. In thick, heavy weather, when lighthouse communication is most needed, it is absolutely worthless. Various lights are important observation points in storms, but no communication can be had with them without a telegraph wire. Instances are cited in which telegraphic communication with the lights would have been invaluable assistance in times of danger. It is to be hoped that this important question will be thoroughly ventilated, and that active steps will be taken to carry some scheme of lighthouse communication into effect.

New Yorkers do not see much of electric railroading, and the electric motor for traction work so far has not made much of a record for itself in this vicinity. The storage battery cars which for a long time were familiar objects on Fourth avenue now decorate a vacant lot. The trolley system has no chance in New York, and even in the suburbs it meets with bitter opposition. For the annexed district it has been rejected so far, although the promoters of the road do not yet despair of convincing the cantankerous residents that the trolley system is what they want. In Brooklyn, after an exciting struggle, it has been firmly sat upon, and altogether there is not much chance for electric traction here until storage batteries or underground conduits come to the rescue. An electric road has recently begun operations between Long Island City and the principal cemeteries in Queen's county. It is worked by the trolley system, and the cars are lighted electrically. The road is a complete success, and may do something toward overcoming the prejudice which exists against the trolley system in this part of the country. In New Jersey an electric road is to be built connecting Newark with the Oranges. Very little work has yet been done, and the company was recently granted an extension of three months' time by the East Orange Township committee.

[illegible] a few days in New York [illegible]. He visited Willet's Point and was shown the submarine harbor defenses of [illegible]. The prince, who is a [illegible] in charge of thirty two [illegible] and [illegible] of [illegible] if [illegible] [illegible] [illegible]

PERSONAL.

E. M. Winters, general manager of the Winters Electric company, Chicago, has gone East on a two weeks' business trip.

A. D. Lundy, of the firm of Sargeant & Lundy, Chicago, was unexpectedly called to Atlanta, Ga., last week, but returned to Chicago last Monday.

B. M. Downs, manager of the Bushwick Glass Works, 83 Fulton street, New York, returned home a few days since after a successful business trip in the West.

C. K. Mead, manager of the Des Moines Water Power company, of Des Moines, Iowa, was in Chicago on July 1st on his return from a business trip to Fort Wayne, Ind.

W. D. Allison, whose withdrawal from the Chicago Telephone company was noted last week, has accepted a position in the railway department of the Thomson-Houston Electric company.

Gustave Monrath has resigned his position as superintendent-electrician with the Monitor Electric company, Chicago. His intention is to open an office in Chicago as consulting and contracting electrical engineer. Mr. Monrath has been a resident of Chicago for several years, and has had quite an extensive experience in electrical work. His early training in electrical science was acquired in the principal cities of Europe, and later with the Edison company in America. Mr. Monrath has the best wishes of a number of friends for success in his new venture.

NEW INCORPORATIONS.

City Traction company, Pittsburgh, Pa.; capital stock, $25,000; operating a street railway by electricity.

Southern Electric company, Lynchburgh, Va.; capital stock, $25,000; electrical and mechanical apparatus and supplies.

Delhi Electric company, Delhi, Delaware county, N. Y.; capital stock, $30,000; to manufacture and use electricity for light, heat and power.

Millville Electric company, Millville, N. J.; capital stock, $50,000; manufacturing, supplying and transmitting heat, light, power and sound.

Shenandoah Electric Light & Power company, Shenandoah, Iowa; capital stock, $15,000; to erect an electric light and power plant at the town of Shenandoah.

Monticello Electric company, Monticello, Iowa; capital stock, $8,000; purchasing, erecting, maintaining and operating an electric light power plant at Monticello.

Lieb Insulating company, Hoboken, N. J.; capital stock, $50,000; to manufacture, buy, sell and deal in electrical machinery and appliances of all kinds and metal goods of all kinds.

Cumberland Illuminating company, Portland, Maine; capital stock, $25,000; supplying light, heat and power by gas and electricity in towns of Westbrook, Deering and Cape Elizabeth, Maine.

Beaver Valley Traction company, Beaver Falls, Pa.; capital stock, $300,000; construction and operation of motors and cables or other machinery for supplying motive power to passenger railways, etc.

Columbus Electric Railway company, Columbus, O.; capital stock, $100,000; constructing, and operating, street railroad in Columbus, to be operated by electric, steam, gas, horse, mule, or other power.

Montana Loan & Realty company, Helena and Butte, Mont.; capital stock, $300,000; general land improvements, including the establishment of electric road and light plants; mines, mining and mine products.

Columbian Medical & Magnetic Battery company, Chicago, Ill.; capital stock, $10,000; to manufacture and sell magnetic, electro-magnetic and electrical batteries and appliances, and medical and surgical supplies.

Westfield Investment & Improvement company, Westfield, Union county, N. J.; capital stock, $50,000; building houses, improvement and sale of lands, maintaining and operating works for the supply of electricity for electric light, heat and power.

Livingston Water Power company, Livingston, Mont.; capital stock, $250,000; buying, selling and dealing in real estate, building and constructing canals and water ditches, manufacture and operate water power, building, constructing and maintaining street and suburban railways and electric light and gas plants, laying water mains, build, maintain, operate, buy or sell factories of all kinds or description, and to do and perform any other acts pertaining to the water or other power.

ELECTRIC LIGHTING.

There are four search lights and 471 incandescent lamps on the United States cruiser Philadelphia.

The Water Front & Amusement company of Elkton, Va., has been organized, and will, it is said, erect an electric light plant.

The city of Rutherfordton, N. C., will hold an election to determine the question of issuing bonds to erect an electric light plant.

It is reported that the electric light plant of the Florence, Ala., Gas, Electric Light & Power company has been sold to W. P. Campbell for $8,000.

The Reno Electric Light and Power company has advertised for bids for the furnishing of timber for the construction of a proposed flume, necessary head-gates and wasteways. It proposes to use water power to drive its plant.

The electric light station at Havana, Cuba, is to be increased so as to have a capacity of 6,000 incandescent lights. The Westinghouse system is used.

W. N. Fishburne, R. G. Wright, W. B. Gerhart and others have incorporated the Waynesboro, Va., Street Railway, Light & Water company to erect an electric light plant and construct a system of water works. The capital stock is to be not less than $100,000.

H. Reaves has leased and will operate the Greenville, Tenn., Electric Light company's plant and increase the capital stock to $10,000. Machinery for a complete alternating electric light system has been ordered from the Thomson-Houston Electric company of Boston.

The Thomson-Houston Electric company of Boston, Mass., is said to have purchased $60 000 worth of stock and $50,000 in bonds of the Capital Electric Lighting company of Nashville, Tenn., and is now reported to be negotiating for the purchase of the entire property.

Work on the "Fair" building is progressing rapidly, men being kept busy at night as well as during the day, the necessary illumination being furnished by the Chicago Arc Light & Power company. As soon as the work has progressed far enough the Sperry company will begin the installment of a permanent plant, which will be complete throughout.

The building of the Washington, D. C., Electric Lighting company at Thirteen-and-one half and B streets now only occupies a portion of the 200 feet frontage which the company owns. The entire property is to be covered with a building which will be just twice the size of the one now in use. The new structure will have a floor space of some 25,000 feet, and will be built in a substantial manner of brick, stone and iron. While the building will be doubled in size the machinery will be tripled in capacity. The company has underground wires laid along Connecticut avenue, Massachusetts avenue, K street and other streets.

According to a press dispatch from St. Louis the lighting situation in that city is becoming serious, and if the town is not confronted with the actual possibility of being left in total darkness there is at least a strong possibility that it will have to enter into new negotiations with the corporation now doing the illuminating, the Municipal Electric Light & Power company. The company has a ten-year franchise to furnish arc lights at $75 a lamp, and, as the company is losing about $25 a lamp a year, affairs are rapidly approaching a crisis. The company's bond is but $50,000, and it is stated that this will be forfeited and the city left to flounder in the darkness or resort to gas, or make a more liberal contract. Suit has been brought against the company by the trustees of Roban Bros., who supplied the boilers, for a balance of $115,000, protected by a mechanic's lien. It is probable that the city will agree to pay a higher price for the 2,000 lights now in use, and thus avoid a disagreeable result.

ELECTRIC RAILWAYS.

The Rochester, N. Y., Railway company has extended its lines half a mile on West avenue.

The electric railway system in East Portland, Ore., is to be extended on G street from Fifth street eastward.

A cable car crushed into an electric car at Pittsburg last week, injuring the motor man and damaging both cars considerably.

The capital stock of the North Avenue Electrical Railway company of Baltimore, Md., has been increased from $50,000 to $100,000.

At Memphis, Tenn., the Citizens' Street Railway company is building a power house that will cost between $40,000 and $50,000.

The Second avenue electric railway of Brooklyn is now in operation. The trip from Fifty second street to Gravesend bay takes 45 minutes.

It is stated that surveys are being made for the construction of an electric railroad between the Warm, Healing and Hot Springs in Virginia.

The Salt Lake City and Rapid Transit street railway companies of Salt Lake City, Utah, are involved in a lawsuit regarding rights of way. Both lines are operated by electricity.

W. R. Hall of Chattanooga, Tenn., and Eugene T. Lynch of New York city have applied for right of way for the building of an electric railway from Memphis, Tenn., to Raleigh Springs at an estimated cost of $125,000.

The contract for the power house of the Queen City Street Railway company of Marion, Ind., has been let. Work must be commenced at once and pushed to completion as fast as possible. The building will be located at the corner of Twenty-third street and Buffalo avenue.

The Santa Cruz, Cal., Electric Railway company has let the contracts for furnishing motor trucks and 110 horse power generator and appliances to the Thomson-Houston Electric company. The electrical construction work was awarded to the California Electrical Works at San Francisco. Everything will be completed and in operation in ninety days. The amount of the two contracts is about $25,000.

The Love Conduit company of Chicago, whose system was described at length in the WESTERN ELECTRICIAN of March 7th, is now constructing a mile and a half of track on what is known as the Fullerton avenue loop of the North Chicago street railway system. This is to demonstrate the practicability of the new system to Mr. Yerkes, who

ELECTRIC MINING.

The [illegible] commenced the operation of its pumps by electricity generated [illegible]

The Edison General Electric company is installing electric drills at the Ute and Ulay mines at Lake City and at the San Bernardino mines [illegible]

The Brown Bear Mining company [illegible] putting in an electric light plant, and will light its mill, mine and buildings with incandescent lights. The engine that runs the mill machinery will furnish the power for the dynamo.

TELEGRAPH.

The telegraph office at Monongah [illegible] from Clarksburg, W. Va., was struck by lightning during a heavy storm a short time ago. James Boyles, the operator, was seriously injured and rendered completely deaf.

The Western Union Telegraph company has won a victory at Milwaukee by a report of the judiciary committee of the common council in favor of an amended ordinance granting the company the right to run its wires overhead in a cable instead of burying them.

Jay Gould says that on June 20th there were 4,645 stockholders in the Western Union Telegraph company, and that 673,262 shares of stock were held by investors and 188 738 shares were in the hands of brokers. Less than a year ago 234,030 shares were in the hands of brokers.

Robert G. Ingersoll is reported as having said that he recently had a secret conference with President Harrison in regard to the proposed establishment of a cable between the United States and Brazil, for the promotion of which Colonel Ingersoll is acting as attorney. The matter is still in its early stages and Colonel Ingersoll was disinclined to give any details.

TELEPHONE.

It is said that Berlin has 16,000 telephone subscribers.

The provincial authorities of Viscay, Spain, have decided to establish a complete system of telephones throughout the province, and to have a telephone station at each of the 122 municipalities which are situated in that energetic and prosperous district of the country.

The telephone line owned by the city of Rochester, N. Y., and running to Hemlock Lake, the source of that city's water supply, thirty miles away, is to be rebuilt at a cost of $6,803.60. The work is to be done within thirty days, and Butler & Riley have the contract.

An English electrical paper states that the Stockholm General Telephone company has established an annual rental rate of $2.75 for instruments in private houses, with an additional toll of about three cents for each conversation. The same paper asserts that in no other European country has the telephone found such an extensive application as in Sweden.

A press dispatch from Columbus, Ind., says: "The telephone service of this city has been practically destroyed by the city's electric light plant, recently put in, on account of the induction. A meeting of telephone patrons and the telephone managers was held last night with the city officials, to see if any remedy could be devised, but no definite conclusions were arrived at. It is impossible to get satisfactory service out of the telephone when the electric lights are burning, and the telephone company will bring damage suits unless relief is given it."

MISCELLANEOUS.

The Corpus Christi, Tex., Electric company has filed an amendment to its charter increasing the capital stock by $10,000.

The Edison General Electric company has declared the seventh quarterly dividend of 2 per cent., payable August 1, 1891.

The first electric boat built on the Continent was recently launched on the Lake of Zurich. It was built by Esscher & Wyss and the Oerlikon Maschinenfabrik. It attains a speed of six miles per hour, and can run five or six hours with one charge of the fifty-six secondary cells carried.

Among the American exhibitors at the Frankfort exposition are the Thomson-Houston company, Boston; Edison United Phonograph company, New York; Westinghouse company, Pittsburg; McIntosh, Seymour & Co., Auburn, N. Y.; Weston Electrical Instrument company, New York; Otis Elevator company, New York.

TRADE NEWS.

Since the latter part of March it is reported that the Sunbeam lamp has been placed on 50 electric street railroads, and has given satisfactory service. The business has greatly increased during that period.

Geo. Cutter is bringing out a simple but very useful device for lowering street lamps. By means of this invention the lamp is drawn to the pole and lowered, taking it

out of the way of trailing and other wires, thus saving much time and annoyance.

Chas. A. Schievren & Co. have secured the order for perforated electric belting for the Columbus Consolidated Street Railway company, Columbus, O.; also for the Worcester, Leicester & Spencer Street Railway company. In the former there are six 13½ inch double belts and in the latter one 10 inch and five 12 inch belts. There is quite a fair demand for the perforated belts for street railway purposes.

At a recent test of steam separators made at Sibley College, Cornell University, under direction of R. C. Carpenter, professor of mechanical engineering, six of the leading separators of the country were put in competition. The issue proved that the Hine eliminator stood far at the head in its efficiency percentage. The Hine Eliminator company, New York, has issued Professor Carpenter's report in neat pamphlet form and will send it on application.

The Creaghead Engineering company has recently been organized in Cincinnati. The work mapped out for the new organization is in the line of consulting and contracting engineers, a specialty being made of electric street railway construction and equipment. The company has secured an agency for the Star Electrix Specialties and other leading supply houses. Mr. Creaghead, the promoter, was formerly with Fraser & Chalmers of Chicago, holding the position of electrical engineer.

The Edison General Electric company has just issued a descriptive circular on small slow speed Edison motors, which it is now pushing. The list of machinery that is at present operated by small electric motors includes small pumps, drill presses and other tools, small fans and blowers, sewing machinery, small lathes, buffing wheels, cloth and paper cutting machinery, organ bellows and printing presses. The Edison company claims that the small motor it is now introducing was specially designed for this class of work.

Owing to the continued increase of business the Thomson-Houston Electric company has again found it necessary to make several changes in the arrangement of departments at the Chicago office. Two years ago the company occupied only one floor of the four-story building on Michigan avenue which at present is required for this extensive establishment. During the past week the engineering and mining departments have been changed to quarters on the first floor, taking the place of the accounting department, which has been removed to more commodious quarters on the second floor. The basement is to be fitted up as an exhibition room, where lighting apparatus, dynamos, motors and mining appliances will be shown.

On June 8th the Baxter Electric Motor company of Baltimore shipped three trucks, with motors attached, to Beatrice, Neb., and on the 12th sent a generator of 80 horse power. At the same time an expert electrician was despatched from the works to put the road in operation, including the erection of the power house. On June 27th the second car was started at 11:30 P. M. The next day, Sunday, 2 500 passengers were handled without a hitch of any kind. This is thought to be unusually quick work. The company has a larger number of orders for cars and motors throughout the South and West. Its electric motor cars are now running in Richmond, Va., Dayton and Cleveland, O., Chicago, Ill., Washington, D. C., and many other places.

The Electrical Supply company is now occupying its elegant new quarters at 102 and 104 Michigan avenue, corner Randolph street, Chicago. Its old address at 171 Randolph street has become so well known among the electrical fraternity that the change will be something of a surprise, but it will only be a question of a short time before the new quarters will be as well known as the old. A large force of men is constantly at work putting in fixtures and placing stock and it will not be very long before the company will be in thorough working order in the new building. A new and improved elevator is now being put in, so that customers may visit all the floors of the store without the inconvenience of climbing stairs. With all the confusion incidental to moving, the large volume of business has not suffered in the least. This company reports very large sales for this season of the year in Sunbeam lamps and other specialties. The Electrical Supply company invites all visiting electricians to call at the new quarters and [illegible] over again.

BUSINESS.

[illegible] of the Mather Electric company [illegible] a new and improved [illegible] catalogue [illegible].

[illegible] Michigan street, Chicago, have just [illegible] Lang's state [illegible]. The slate bases [illegible], were com-pleted, the switch-board will be the finest ever built in this city.

[illegible] Manufacturing company, Chicago, is having an [illegible] work.

[illegible]

Wm. Crompton, general manager of the Economic Lamp company of Boston, visited Chicago last week. He expressed himself as highly pleased with the management of his Chicago agency, the sales having reached a point entirely beyond his expectation. While competition has been strong Mr. Kirkham of the Northwestern Electric Specialty company has sold the Economic lamp since May 1st, in over one hundred western cities and towns.

H. S. Walker has recently sold to the Elkhart Electric Street Railway company a Beck engine of 125 horse power capacity and one of 50 horse power to the Goodrich Transportation company, to run a Mather plant in the new steamer Virginia, which is nearly completed at Cleveland, and which is to be put in service between Chicago and Milwaukee in a week or so. Mr. Walker reports a very fine midsummer business in the different lines of machinery which he represents.

S. Taussig, 45 River street, Chicago, has gladly complied with a large number of requests coming from within 500 miles of this city for free thermometers advertising his Synovial Dynamo oil, a notice of which recently appeared in this paper; but when Anderson, S. C., and Tacoma, Washington, were heard from he was tempted to think it was time to draw the line. Mr. Taussig has taken the western agency for a little device for cutting water tube glasses that apparently has considerable merit. He still has a supply of thermometers on hand, which will be sent free to any one applying. He would particularly like the address of stationary engineers who need a thermometer and to whom he could send circulars advertising his new glass tube cutter.

J. D. Claghorn, manager of the Chicago Electric Manufacturing company, 73 West Jackson street, has recently added several pieces of new machinery to his factory, and now it would seem that everything necessary in any line of electrical work has been secured. During the past month a room has been set apart for the repair of fine electrical apparatus, fitted up with a specially wound No. 2 Edison dynamo, having a capacity of 30 amperes at 125 volts, to be used for testing, recalibrating, etc., with 10 cells of Anglo-American storage battery connected in parallel so that 200 amperes can be secured. This room is provided with a fine Wheatstone bridge, galvanometers and other apparatus necessary for the repair of low current ammeters and voltmeters of high and low tension, both alternating and direct current. E. W. Hammer, late general superintendent of the Ottumwa, Iowa, electric street railway system, has been engaged and will have immediate charge of this portion of the factory. Mr. Claghorn is now building to order a 500 ampere meter, and hereafter will devote more of his time to the detail work of the factory.

ELECTRICAL PATENTS.

Issued June 30, 1891.

454,867. Electrical Transmission of Telegraphic and Time Indications. Henry J. Haight, New York, N. Y.

454,873. Carbon for Electric Arc Lamps. Washington H. Lawrence, Cleveland, O.

454,881. Overhead Electric Conductor System. Gordon J. Scott, Minneapolis, Minn.

454,882. Electro Dynamic Machine. Gordon J. Scott, Minneapolis, Minn.

454,883. Motor Generator or Transformer. Gordon J. Scott, Minneapolis, Minn.

454,884. Printing Telegraph Instrument. Frederick Sedgwick, Chicago, Ill.

Claim seventeen follows:

"17. The combination, with a main line and electro generator, of a series of synchronous motors, a series of printing instruments having rotating type wheels, screw shafts and coating mechanism, as described, in said respective instruments for shifting said type wheels laterally, a normally shunted magnet, armature, rock shaft, and gears, as specified, for transferring the motor power from the type wheel shaft to said screw shaft, and means, as set forth, for breaking said shunt circuit at a predetermiued time."

454,888. Electric Car Motor Jacket. John Stephenson, New York, N. Y.

454,890. Apparatus for Removing Inductive Effects from Electric Lines. Elihu Thomson, Lynn, Mass.

Claim three is:

"3. The combination of two or more inducing electric lines and two or more telephone circuits inductively affected thereby and each provided with a counter inducing coil or induction generator placed in a composite air field produced by the two inducing line, each counter-inducing coil or generator for a telephone line being located in position to be out of inductive relation to the coil or generator for other telephone line."

454,897. Time Lock. George W. Adams, Malden, Mass.

454,903. Means for Connecting Trolley and Feed Wires. John R. Fletcher, Chicago, Ill.

454,904. Aerial Cut-Out. John R. Fletcher, Dayton, O.

454,921. Hotel Indicator. Frank B. Wood, New York, N. Y.

454,926. Protector for Use in Electric Circuits. William H. Clausen, Melrose, Mass.

454,[illegible]. Method of Laying Electric Conduits. Alexander C. Chenoweth, New York, N. Y.

454,[illegible]. Means for Constructing Electric Conduits. Alexander C. Chenoweth, New York, N. Y.

454,949. Electric Meter. Herbert M. Pilkington and Roger S. White, Brooklyn, N. Y.

454,[illegible]. Electric Current Regulator or Rheostat. Charles D. [illegible], U. S. Navy, and Thomas Haywood and Frank [illegible] Anderson, Exeton, Md.

454,973. Electric Signaling Apparatus. Morris Martin, Malden, Mass.

454,974. Circuit for Electric Signaling. Morris Martin, Malden, Mass.

454,979. Electric Heater. Charles W. Drew and Edward R. Francis, Minneapolis, Minn.

In this invention the current is made to pass through resistance coils of a rheostat arranged near the heating surface, in this manner utilizing any heat generated in the coils of the rheostat.

454,985. Electric Temperature Controller. Emer H. Parker, Evanston, Ill.

454,995. Electric Switch. James Des Brisay, New York, N. Y.

455,005. Circuit Closer for Burglar Alarms. Don A. Palmer, Chicago, Ill.

This invention consists in a slotted sash pulley frame provided with suitable insulated contact points and a circuit closer adapted to make or break the current by the movement of the sash end over said pulley.

455,010. Electric Soldering Iron. Arthur E. Appleyard, Boston, Mass.

The soldering iron is heated by means of a conducting loop of platinum wire connected with a suitable source of electrical supply.

455,016. Electrical Annunciator. William F. Harte and Clifford A. Gerold, Omaha, Neb.

455,019. Circuit Connection for Electric Car Motors. Arnold A. Ingraham, New York, N. Y.

455,037. Apparatus for Boring Wells. Fulton Gardner, Chicago, Ill.

Claim two reads:

"2. The combination with a revolving boring tool of an electric motor having a revolving armature connected to the boring tool, a locking or holding device consisting of radially moving jars adapted to engage the walls of the well for holding the field magnet of the motor from revolving, an extensible or telescoping connection located between said holding device and said boring tool to permit the feed of the latter, and jars for operating said holding device."

455,041. Electric Clock for Use in Electric Lighting and Other Systems. Friedrich von Hefner-Alteneck, Berlin, Germany.

455,055. Electric Time Denoting Device. William Ramsay, Washington, D. C.

455,067. Electric Magnetic Motor. Nikola Tesla, New York, N. Y.

455,068. Electrical Meter. Nikola Tesla, New York, N. Y.

455,069. Electric Incandescent Lamp. Nikola Tesla, New York, N. Y.

Claim three reads:

"In an incandescent electric lamp the combination with a globe or receiver exhausted to the non-striking point of metallic wires sealed therein, a refractory body mounted on or electrically connected to each wire, the said wires within the globe and such parts of the refractory body as are not to be rendered incandescent being coated or covered with insulation."

455,071. Clutch for Arc Lamps. Frank H. Thompson, Philadelphia, Pa.

455,075. Printing Telegraph. Henry Van Hoevenbergh, New York, N. Y.

455,086. Push Button. Granville W. Wright, New Haven, Conn.

455,087. Electric Arc Lamp. Craig R. Arnold, Chester, Pa.

455,092. Automatic Electric Switch. Carl O. C. Billberg and Paul A. N. Winand, Philadelphia, Pa.

455,107. Insulator. James F. Munsie, Brooklyn, N. Y. Filed March 28, 1890.

455,109. Electric Motor. F. L. McGahan, Indianapolis, Ind.

455,110. Electric Motor. Frederick L. McGahan, Indianapolis, Ind.

455,126. Electric Postoffice Box. Will A. M. Smith and Robert T. F. Smith, Morrison, Ill.

455,138. Electric Signal for Steam Vessels. Dyson D. Wass, San Francisco, Cal.

455,164. Apparatus for Extracting Gold and Silver From Their Ores by Electrical Amalgamation. George Button and William E. Wyeth, Kimberley, Griqualand West, South Africa.

455,176. Apparatus for Automatically Regulating the Firing of Ordnance on Ships. Manuel J. Cuadros, Liege, Belgium.

455,187. Filament for Incandescent Electric Lamps. George Erlwein, Berlin, Germany.

455,223. Lightning Arrester. Frank Mansfield and Chas. W. Wason, Cleveland, O.

455,233. Electric Railway. James F. Munsie, Brooklyn, N. Y.

455,234. Electric Railway. James F. Munsie, Brooklyn, N. Y.

455,266. Electric Railway Signal. Winslow Stevens and Henry J. Hovey, New Haven, Conn.

455,267. Automatic Regulator for Electric Motors or Dynamo Electric Machines. Schuyler S. Wheeler, New York, N. Y.

455,268. Telethermometer. Frederick W. Wiesebrock, New York, N. Y.

455,287. Socket for Incandescent Electric Lamps. Benjamin B. Keyes, Chelsea, Mass.

455,294. Printing Telegraph. David H. Bates and Henry Van Hoevenbergh, New York, N. Y.

EUGENE F. PHILLIPS, President. W. H. SAWYER, Sec'y and Electrician.

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and is **guaranteed to be waterproof, and will not deteriorate, oxidize or crack**, and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

DICTIONARY

—OF—

ELECTRICAL WORDS, TERMS AND PHRASES.

By EDWIN J. HOUSTON, A. M.

656 Pages. 397 Illustrations. Cloth Binding. Price, postage prepaid, to any part of the world, $2.50.

This Dictionary includes over upon 2,500 distinct Words, Terms or Phrases. Each of the great classes or divisions of electrical investigation or utilization comes under careful and exhaustive treatment. For some reasons it deserves rather to be called an Encyclopædia than a dictionary.

The Scheme of Treatment is as follows:

1st. The words, terms and phrases are invariably followed by a short, concise definition, giving the sense in which they are correctly employed.

2d. A general statement then follows of the Principles of Electrical Science on which the definition is founded.

3d. When, from the complexity of the apparatus, or from other considerations, it has been thought desirable to do so, an Illustration or Diagram of the apparatus is given.

4th. To facilitate study, an elaborate system of Cross References has been adopted so that it is as easy to find the definitions as the words, and aliases are readily detected and traced.

In applying these rules great care has been exercised to secure CLEARNESS, to the end that while the definitions and explanations shall be SATISFACTORY TO THE EXPERT ELECTRICIAN, they shall also be SIMPLE AND INTELLIGIBLE to those who have had no training at all in electricity, or are novices in the art.

"MERIT LEADS TO SUCCESS."

HEISLER

LONG DISTANCE SERIES INCANDESCENT LIGHTING

HAS NO EQUAL.

ONLY successful method of distribution covering a large area WITHOUT swamping the plant with INTEREST on Copper Wire or cost of FUEL.
Transformers or Converters are a CONSTANT source of TROUBLE and EXPENSE, will cost MORE for repairs in a year than to renew the Lamps by our system.
Our PLANTS can be operated with success ELECTRICALLY and FINANCIALLY where no others can.
Plan of wiring SIMPLE, CHEAP and EFFICIENT.
LAMPS from 16 C. P. up, noted for BRILLIANCY and BEAUTY of the light.
ALSO SERIES LAMPS of any C. P. for Arc Light Circuits.
Gold Medal, Paris Exposition, 1889.
Estimates furnished on application, for erection of plants in any section. Correspondence solicited.

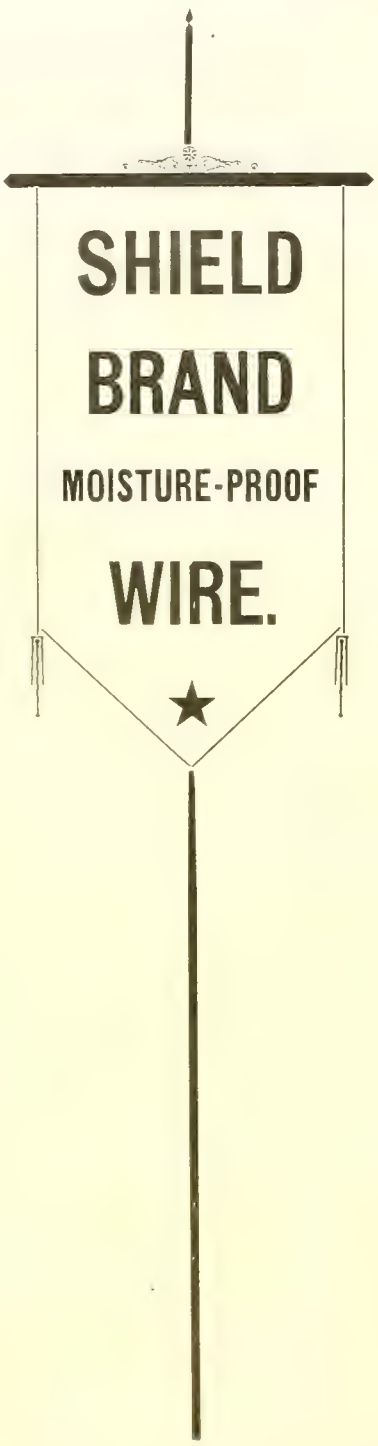
CHICAGO.



We don't Believe

That we can convince you, with mere blatant phraseology, that Shield Brand Wire is any better than its rivals.

You do Believe

Facts, and we offer a few for your consideration, appropriately framed. A test was made, taking about fifty feet of our standard insulation.

Here is the picture:

	NO GROUNDS. NO ACCIDENTS.	
NO UNSATISFACTORY SERVICE.	50 ft. of Shield Brand Moisture Proof At immersion, 200 Million Ohms. After 24 hours, 5,000,000 Ohms. After 72 hours, 5,000,000 Ohms. After 120 hours, 4,850,000 Ohms. One week, 4,200,000 Ohms.	NO UNDERGROUND AGITATION.
	NO UNNECESSARY CONSUMPTION OF FUEL.	

We made THAT test—now if you please, allow us to suggest that YOU make one. Take about three or four feet of "Shield Brand," and attempt to abrade or destroy the covering. Scrub it across a tree or a sharp corner and learn how long it takes to ruin the insulation. Again, take a short piece and wobble it until the wire is broken INSIDE and note the result.

DOUBLE CARBON LAMPS

Afford the Only Reliable and Efficient Means for

ALL NIGHT ELECTRIC LIGHTING.

All other devices are crude, expensive, and unsatisfactory.

THE BRUSH ELECTRIC COMPANY

Has established its broad foundation patent for Double Carbon Arc Lamps, No. 219,208, having *won four distinct infringement suits* in the United States Courts, two of them on final hearing, the decisions being rendered by Judges Gresham, Blodgett, Brown and Ricks.

The public is warned against the use of infringing lamps or any crude substitute for the Brush invention.

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, unequaled for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Vol. IX. CHICAGO, JULY 18, 1891. No. 3

Triplex Electric Pumps.

The pumps as shown in the cuts consist of three vertical cylinders, within which are three self-acting plungers, their cranks being hung from the main shaft at an angle of 120°, in order to produce the most even application of power.

The advantages and adaptability of the triplex or three cylinder pumps for electric pumping are found in the fact that the pump offers absolutely even and unvarying resistance to the motor under all conditions and consumes but minimum power in friction.

The first effect is contributed by the action of three-throw crank shafts, in whose stroke there is positively no dead center or point of varying load productive of jerky motion and attendant vibration or water hammer; while the second effect is the happy result of combined ingenuity and skill in production.

Fig. 1 represents a pump with cylinders 6½ inches in diameter and 8 inch stroke with a capacity of 100 gallons per minute against 150 pounds' pressure.

Fig. 2 represents a pump with cylinders 8-inches in diameter and 8 inch stroke with a capacity of 200 gallons per minute against 150 pounds' pressure.

Thomson Houston motors of 7½ horse power and 20 horse power respectively are connected to the pumps by spur gearing. There are rawhide pinions on the counter and motor shaft.

This pump is manufactured by the Gould Manufacturing company of Seneca Falls, N. Y. Tests were made with a 15 horse power motor of special winding with a view to determining the general fitness of the type for deep-mining pressures, and the results have been considered sufficiently satisfactory to warrant the building of a standard line of pumps of from 50 to 500 gallons per minute capacity.

The Gould Manufacturing company intends to build pumps of the same type for pressure upward to 300 pounds, thus making it possible to pump from the lowest levels of mines against a head of upward of 700 feet.

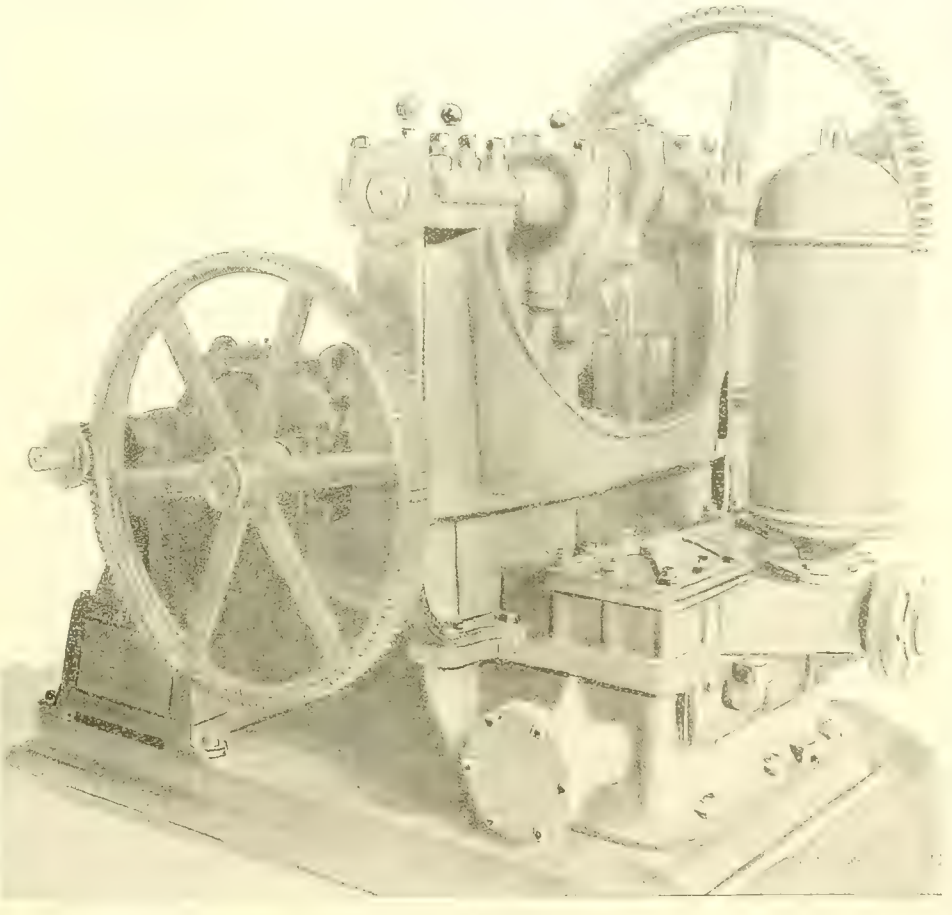

FIG. 1. TRIPLEX ELECTRIC PUMPS.

Thomson-Houston Co. and the Chicago West Side Road Syndicate.

Reports, purporting to come from reliable sources, have been circulated in Chicago and New York connecting the Thomson-Houston Electric company with the syndicate controlling the West Side Elevated railroad. B. E. Sunny, when questioned by a representative of the WESTERN ELECTRICIAN, stated that if any negotiations had been entered into, either for the control of the West Side elevated road or for its equipment with electric power, the business had been carried on through the company's eastern office, and the Chicago branch had heard nothing in regard to it. "Naturally we would have been notified of any such transaction," said Mr. Sunny, "and I therefore regard the report as incorrect."

At the New York office nothing was known of the alleged deal, although the rumors had been quite extensively circulated in electrical circles and on Wall street.

Telegraph Poles in New Orleans.

In the last issue of the WESTERN ELECTRICIAN reference was made to the action of the city council of New Orleans in ordering electric wires removed and poles chopped, and the prompt obedience of the mayor. A press dispatch announces a new turn in affairs. It says: "The Streets and Landings committee of the City Council discussed to-day the request of the Postal Telegraph company to be allowed to put under ground the wires cut down by the mayor. The company presented a special report from experts that the high wire towers upon which it is proposed to string the wires and which it was ordered to use are dangerous even in their present condition, and to string any more wires on them would make them more so. The committee seemed impressed by this showing. It refused, however, to allow the company to use the subway or underground system, and authorized it to erect the ordinary poles for its wires wherever they were necessary, thus pronouncing against both the tower and the underground subway systems, and in favor of the old pole nuisance as the only safe way of stringing telegraph wires."

Canada's International Exhibition.

The electrical features of the Canadian exhibition at St. John, N. B., this year promise to excel all former displays. The preparations for the event are on a more elaborate scale than heretofore, and the management feels warranted in announcing that the exhibition will not only be a great display of electrical and general mechanical appliances but that it will assume the nature of a grand fete. The municipal authorities are making elaborate preparations for the event, and they promise that the city will be arrayed in holiday attire to receive visitors. There will be plenty of attractions to afford amusement and entertainment to strangers in addition to the [illegible] the new opera house now nearly completed it is promised there will be light opera and attractive theatrical arrangements have been made in the St. Andrew's and Palace rinks, as well as Jack's hall. One of the features which will be particularly attractive to lovers of art will be the art exhibition and sale, which is to be held during the exhibition, opening on September 23d and closing October 3d. The promoters of this department have established correspondence throughout Canada, United States, Europe and Australasia, and have the prospect of having one of the best art exhibitions ever held in Canada.

The Moosepath Driving Park association is preparing a very fine programme of races. During the year it has expended a large amount of money improving the course. It is also understood that the Neptune Rowing Club proposes to organize for regattas in which there will be some novel features introduced. No doubt the Amateur Athletic association and the Shamrock club will utilize their splendid grounds for some interesting sports.

As to the exhibition proper it is gratifying to note that it is maintaining its international character, and in addition to the applications from the maritime provinces a number of applications for space have been received from the United States, England, Germany and Italy. It is also anticipated that there will be a very comprehensive Spanish exhibit. Some of the most attractive displays from the Jamacia exhibition are now assured for the St. John's exposition.

Arrangements are being made with the best musical talent for promenade concerts every afternoon and evening during the term of the exhibition. Pyrotechnic displays will be another feature. Machinery hall will be made far more attractive than at any previous exhibition, as it is expected that only machinery in motion will be shown there. Arrangements are in progress for a special electrical display. There is much in and about St. John to attract the electrical engineer. The city is one of the most brilliantly illuminated municipalities in the dominion. There are five central stations, in which Edison, Thomson-Houston, Fort Wayne and Brush plants are installed. In addition the city is now running electric lights of its own in the North End, where it has a Brush plant. D. W. Clark & Son are running the Brush system in the West End, and the New Brunswick Electrical [illegible] company, operating the Fort Wayne system, has completed arrangements for lighting the East End.

Another traction company has been formed in Pittsburg by the syndicate headed by H. Sellers McKee. James A. Chambers, M. A. Verner, Edward E. Denniston and John P. Isley are associated with Mr. McKee. The capital stock of the new company is $1[illegible]. The promoters of the project are interested in many electric street railways throughout the country, notably the Rochester, N. Y., and Buffalo system.

Proposed Electric Road between Chicago and Milwaukee.

Quite a sensation was created in Milwaukee and Chicago last week by the incorporation of the Inter-State Electric Railway company in the former city. The new company, which was capitalized at $10,000,000, at once announced its intention of building an elevated electric railway between Milwaukee and Chicago, and of making the trip between those points in just one hour. The distance is eighty-five miles, and to make the trip in an hour would mean a speed of about a mile and a half a minute. No small amount of incredulity was expressed concerning the enterprise.

The incorporators are G. J. Cox, Portage, Wis.; F. A. Deleglise, Antigo, Wis.; Ira C. Edwards, St. Paul; Charles T. Goodrich, Chicago, and J. W. Dickinson, C. E. Cain and Robert H. Clark, Milwaukee. None of them seem to stand very high in the world of finance. Mr. Deleglise is well-to-do. Mr. Goodrich of Chicago is said to be an electrician, but nothing is known of him in financial circles. The general public has known nothing about the Milwaukee incorporators until the present time. Mr. Cain is an inspector of some kind, Mr. Dickinson is a manufacturer of ash boxes, and of Mr. Clark nothing is known. Mr. Edwards of St Paul is a telegraph operator, and has been more recently engaged in the insurance business. The incorporators claim, however, that wealthy men of Milwaukee, Chicago and St. Paul are backing the enterprise, and that work will be well under way before a year elapses. The capital stock of $10,000,000 is divided into 100,000 shares, 80,000 of preferred and 20,000 of common stock. The management, it is announced, will be in the hands of the incorporators for some little time. The headquarters will be in Milwaukee. The road, it is asserted, will be running before the opening of the World's Fair.

It is claimed by the incorporators that they have the exclusive use of two patents, which will contribute materially to the success of the enterprise. [illegible] prise the conductor of any [illegible] for [illegible] passing [illegible] a [illegible] speed [illegible] be [illegible] rates [illegible] [illegible] is the property of Mr. Cain. [illegible] and each track will consist of three rails, the middle rail being used as [illegible] It is proposed to build three power houses, one at Milwaukee, another at Chicago, and the third at some intervening point. policy of the association as regards the exhibit, and several prominent electricians have promised to address the meeting.

The Monrath-Devold System of Rope Transmission for Electric Car Trucks.

In the WESTERN ELECTRICIAN of October 18, 1890, there was presented a discription of F. Devold's system of power transmission. This invention, as applied to dynamos, Figs. 1 and 2, consists of a combination of rope and friction transmission so arranged as to reduce friction in

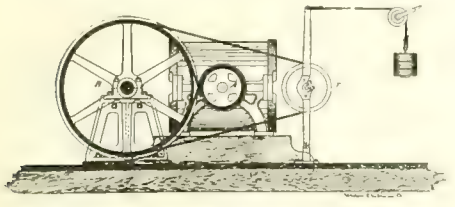

FIG. 1. MONRATH-DEVOLD SYSTEM OF ROPE TRANSMISSION FOR ELECTRIC CAR TRUCKS.

the bearings of both dynamo and main shaft to a minimum. Both pulleys have two or more grooves for the rope and a 2 or 3 inch projecting friction flange on each side. The dynamo, Fig. 1, is placed with its pulley *A* against the driving pulley *B* on the main shaft, as in the case of ordinary friction transmission; but the pulleys, although in contact, do not press hard against each other. A rope is thrown two or three times over both pulleys in the direction shown in Fig. 1, and back to a rope tightener *T*, some few feet behind the dynamo. When the rope is straightened the friction of the rope and the friction of the two pulleys, increased by the pulling rope, will transmit the power, and as the pull of the rope and the press of the flanges are working in opposite directions the loss of energy is materially reduced. In Fig. 2 is shown more clearly the arrangement of the ropes on the pulleys.

Since the publication already referred to, F. Devold and Electrical Engineer Gustave Monrath of Chicago have together devised an application of the system to electric motor cars, and the illustrations Figs. 3, 4 and 5 show the new construction as adapted to the Westinghouse truck.

In making the new application the main object of the designers was to avoid the use of objectionable gearing and to protect the motor against the danger of burning out. The features of the truck as now arranged will be better understood after reference to the lettered parts in Fig. 3, which is a plan view of the Westinghouse truck, fitted out with the Monrath-Devold rigging in connection with a single reduction motor. Fig. 4 is a sectional side view of the truck.

From the cuts it will be seen that a combined rope and friction transmission is employed in which there is a special arrangement in the pulley on the wheel shaft whereby the connection between the motor and truck is rendered flexible. This construction is shown in detail in Fig. 5.

In the plan view *a* represents the pulley on the armature shaft, having in it two or three deep grooves for guiding the rope *b* and also provided with two friction flanges, each about 1-5 the radius of the pulley in width. The flanges of this pulley are in close contact with the flanges of the pulley *c* on the wheel shaft, without pressing too hard against them. The pulley on the wheel shaft is, so to speak, a double pulley, the outside of which has the same proportional shape as the armature pulley. The rope is wound two or three times around both pulleys in opposite directions and back to a rope tightener *d*, which is fastened in a double bracket supported by the

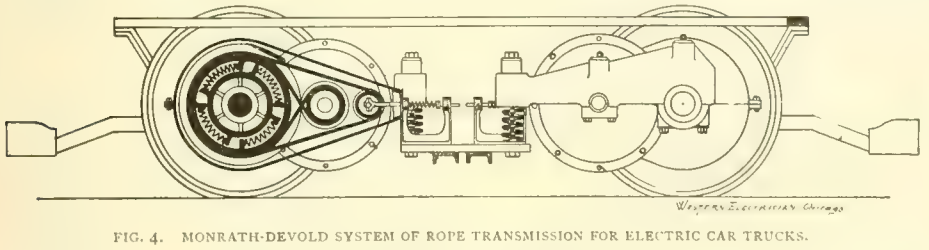

FIG. 4. MONRATH-DEVOLD SYSTEM OF ROPE TRANSMISSION FOR ELECTRIC CAR TRUCKS.

cross bars of the truck. The rope tightener is furnished with a spring *s* and double adjusting nuts *n*. A sheet iron cover *c* made in two parts surrounds both the pulleys and the rope tightener, leaving the adjusting nut free and easily accessible in case the rope needs tightening.

It is claimed for this combination transmission that the power transmitted by the rope with a double turn on the pulleys only amounts to 1-5 of the total power transmitted, and that the friction between the flanges of the pulley produced by the pull of the rope is sufficient to transmit the remaining 4-5 of the power, consequently the size of the rope can be proportionally very small. It is asserted that in the case of the Westinghouse motor the strain on the rope, if ¾ inch in diameter, will not amount to more than 40 pounds or 1.32 per cent. of the breaking strain.

To secure an easy start of the motor there is provided the special arrangement on the truck pulley already referred to and illustrated in Fig. 5. In the cut, which is a sectional view of this double pulley, *A* is the interior part. This is keyed on the shaft and has a concaved rim *a*. This rim *a* is equally divided by four lugs as shown in Fig. 4. The outside portion *B* of this combination pulley has the hub bored out ¼ of an inch larger than the shaft, and the inside of its rim is rounded out in a manner similar to the rim of the inside part. When the two parts are brought together the cavities in both form a hollow spring chamber divided in four sections by the lugs protruding from both parts. In each of these chambers there is a steel spiral spring kept in place by a semicircular projection on the side of the lugs facing the spring. To insert the springs the collar *s* is loosened and the outside part of the pulley drawn toward the truck wheel. The springs are placed between the lugs and a quick push will make the pulley snap together. To prevent the backs of the lugs from striking hard against each other, rubber balls are inserted. By this arrangement it will be seen that the motor will have the benefit of turning one half of a revolution, or even more if desired, before the springs are pushed so tight as to set the car moving. When started the car and the motor will both be riding on the spring, and this interposition of a flexible medium will serve to counteract the effect of jerks caused by the unevenness of the track.

In case the current is suddenly thrown off the motor, the momentum of the armature will be strong enough to prevent the springs from turning the armature back. It is claimed also that the springs and the rope, which are the only part of the transmission apparatus that will wear out, will easily outlast the best gear-wheel, and the quick way of replacing either is superior to the old system. The spring arrangement, as will be understood, may be adapted for gearless motors as a means of connecting the armature with the wheel shaft.

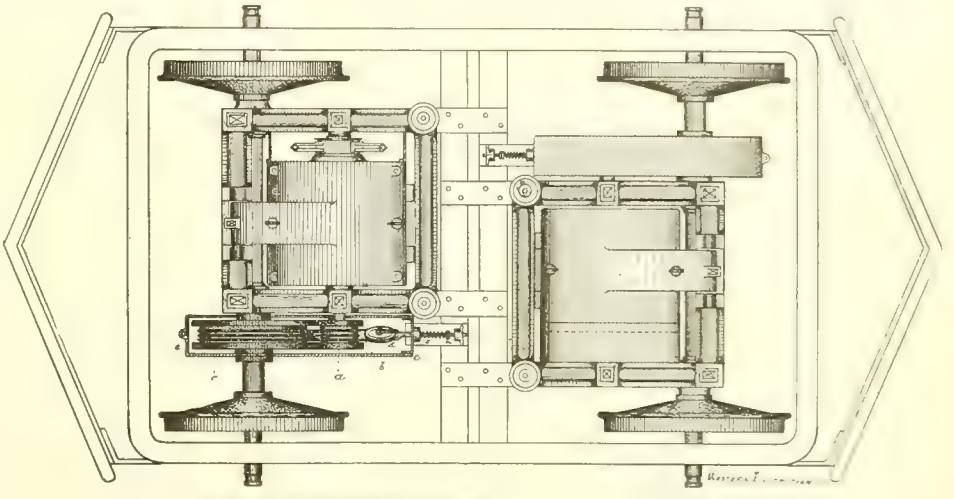

FIG. 3. MONRATH-DEVOLD SYSTEM OF ROPE TRANSMISSION FOR ELECTRIC CAR TRUCKS.

Quarrying at Night by Electric Light.

At Hawthorne, about seven miles from the Union depot, Chicago, on the C., B. & Q. railroad, the visitor will find an industry which constitutes a good-sized village in itself. This is the large stone-quarrying plant of Dolese & Shepard. Hitherto the firm has given employment to some 480 men, turning out about 120 carloads of finished material each day. But within the last two weeks the feature of working by night has been introduced. A Thomson-Houston dynamo of 12,500 watts capacity has been installed. This dynamo supplies twenty-six 2,000 candle power, double-carbon lamps. The lamps are hung from a pivoted arm so that they can be swung in any direction desired. Further than this, at every blast the enlargement of the circular pit necessitates the removal of the lights to a new

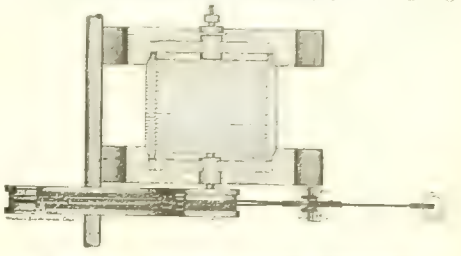

FIG. 2. MONRATH-DEVOLD SYSTEM OF ROPE TRANSMISSION FOR ELECTRIC CAR TRUCKS.

ballasted by rocks to keep it fixed in the required position. W[illegible] being dumped from the platforms, they are easily carried to the new position, the slack wire which has been coiled, being let out to the requisite length. The lights, which are in use at only one of the blasting pits, are giving eminent satisfaction. An interesting fact is brought out, from the comparison of the average work per man during the day and night. From the figures given by the foreman it seems that the company employs about 480 men and the works have a capacity of 120 carloads per day, while 90 men are employed at night the works having a capacity of 30 carloads. From these figures it would seem that three night workers can do the work of four day workers; in other words, the capacity of the night worker is one-third greater than that of the day worker. Reasons for this may be attributed to the greater freedom and ease of the night worker owing to more space and a much cooler atmosphere. No doubt many large concerns would find it to their advantage to follow the example of Dolese & Shepard.

The Marquette City and Presque Isle Railway company, which is operating the Thomson-Houston system, has recently been put in operation. This line comprises three miles of track and is at present operating three motor cars. This is the first road in Michigan equipped by the Thomson-Houston Electric company, and if its first day's operation is any criterion for what is to follow [illegible] nently successful.

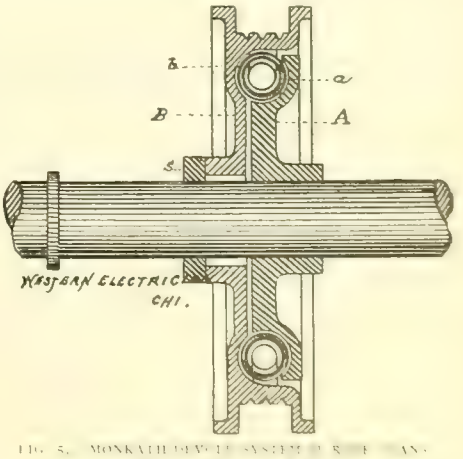

FIG. 5. MONRATH-DEVOLD SYSTEM OF ROPE TRANSMISSION FOR ELECTRIC CAR TRUCKS.

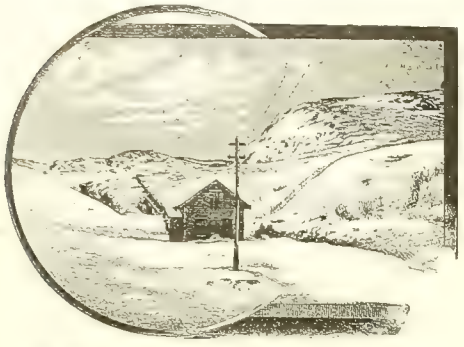
Electric Light Plant in the Land of the Midnight Sun.

The WESTERN ELECTRICIAN has already referred to the electric light station at Hammersfest in Norway, the most northern city of the world, where, during the long winter night, the sun never rises above the horizon for many days. The accompanying illustrations are views of the barren but picturesque surroundings of the plant.

It is the Thomson-Houston system which has the credit of being installed nearest the north pole. The equipment consists of two radial turbines with horizontal shafts, placed about one mile from the city, at a waterfall of great volume.



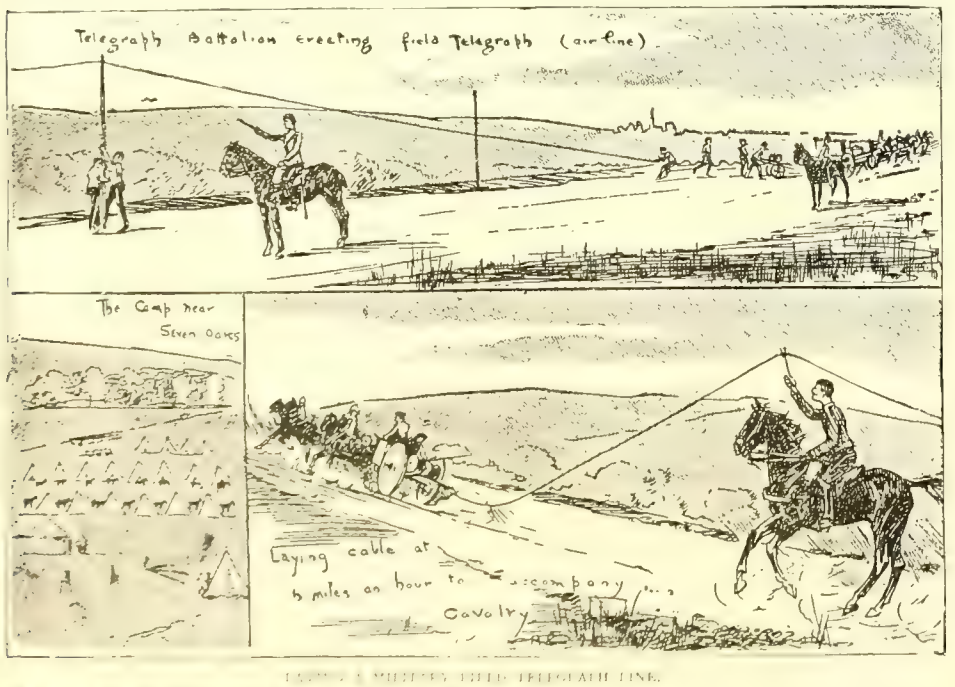
ELECTRIC LIGHT PLANT IN THE LAND OF THE MIDNIGHT SUN.

One of these turbines is directly connected to a Thomson-Houston arc dynamo furnishing current to eighteen 7 ampere arc lamps. The lamps are supported on poles very substantially set so as to resist the damaging hurricanes which prevail in this region during the winter. The second and larger turbine, which was recently put in, is intended to drive a 600 light, 16 candle-power alternating current Thomson-Houston incandescent dynamo. This machine is to furnish current for lighting residences and the public buildings. The plant is owned by the city, and the arc lamps which have been in operation during the last winter have, it is stated, given satisfaction.

One of the cuts shows the power house and the other one of the arc lamps serving as a light for the harbor. The illustrations are reproduced from *Elektrotechnische Zeitschrift*.

Laying a Military Field Telegraph Line.

The first division of the Royal Engineers, Telegraph Battalion, now encamped at Chevening, close to Lord Stanand Chatham. For laying such telegraph lines to accompany cavalry, a light cable is made use of. As will be seen from the accompanying sketch the cable is carried on reels on a wheeled cart. It can be laid, it is stated, at the rate of six to seven miles an hour. The Telegraph Battalion of the Royal Engineers comprises two divisions. One is employed in time of peace under the postoffice in the construction and maintenance of postal lines; the other, stationed at Aldershot, is equipped with field telegraph material. The cut is from the London *Daily Graphic*.



LAYING A MILITARY FIELD TELEGRAPH LINE.

The Incandescent Lamp Suit Decided in Favor of Edison.

The suit of the Edison Electric Light company against the United States Electric Light company in the United States circuit court, is reported as we go to press to have been decided in favor of Edison. According to F. S. Hasting, secretary of the Edison General Electric company and the Edison Electric Light company of New York, the decision was handed down by Judge Wallace on the morning of July 14. As is well known this suit was based on what Edison claimed was his fundamental patent on a filament of high resistance The court orders an injunction restraining the United States Electric Light company from making any more incandescent lamps. The court also orders an accounting for the purpose of ascertaining the profit on all lamps which the defendant company has heretofore made and sold.

Interesting Plant at Weehawken.

The members of the New York Electrical society after the annual meeting last week accepted an invitation to visit Weehawken and inspect the plant of the Palisades Amusement company. They found much to interest and entertain them.

The visitors found that electric lighting had not been altogether neglected. There are 150 arc lamps scattered about the grounds.

The station in which the plant is erected is a two story frame building which stands in a hollow in the rear of the ground back of the grand stand. It is conveniently arranged for water supply and also for receiving fuel from the main road by means of two chutes delivering direct into the boiler room.

The second story of the station is equipped as a store room and repair shop, with a testing room for lamps.

There are three Thomson-Houston arc dynamos, each having a capacity of 53 lamps. The lights are arranged on three circuits.

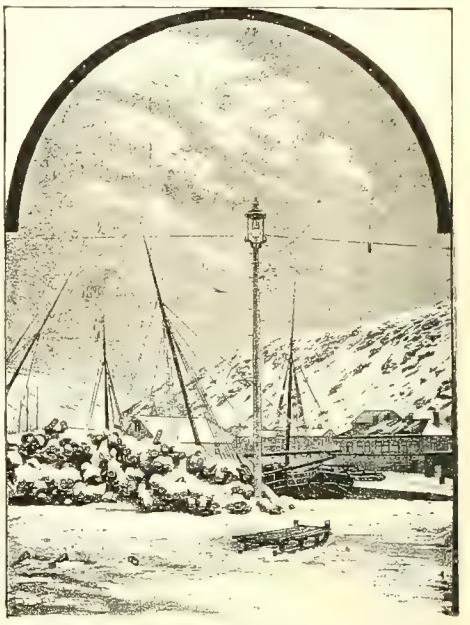
Number 1 circuit controls every other light on the grand stand, in the buildings on the bluff fronting the river at the back of the stage, the lights at all the entrances, a few of the lights about the ground and the lights in the towers of the restaurant building.

Number 2 circuit takes in the intermediate lamps and a portion of the lights on the stage.

Number 3 circuit is woven in and out of circuits number 1 and 2 so that in case of accident to a machine or circuit there will be no part of the ground which will be in darkness, and all important points where crowds gather are covered by the lights of the several circuits.

The lights at the entrances to the grand stand have colored globes upon them to indicate the passages and the towers of the restaurant building are colored, producing a beautiful effect from the river.

There is also installed one Thomson-Houston incandescent dynamo of 700 16 candle power capacity. This supplies the incandescent lamps under the grand stand, in the castle, in the restaurant building, the offices, ladies' reception building, the orchestra and dressing rooms under the stage. The dynamo is of the low tension, direct current type, with automatic regulation, being compound wound. The total num-



ELECTRIC LIGHT PLANT IN THE LAND OF THE MIDNIGHT SUN.

ber of lamps already arranged for is 628. It is proposed to change a number of the 16 to 10 candle power lamps to enable a further increase of the present plant.

The engines are of the McIntosh & Seymour automatic type. One is rated at 60 horse power and drives two arc dynamos; the other is rated at 90 horse power.

There are two 80 horse power single return tubular boilers, working at a pressure of 90 horse power per square inch, and tested to 160 pounds water pressure. The boilers are furnished with heavy cast iron fronts. The engines and boilers, and in fact the whole steam equipment, was installed by Pierce & Thomas of 42 Cortlandt street, New York.

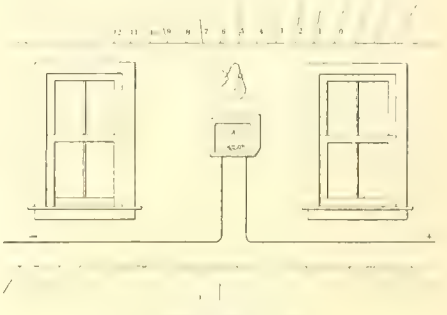
There is one 4½x2⅞x4 inch Worthington & Knowles duplex boiler feed pump with ample capacity to feed the two boilers, and an injector.

There is one number 11 brass coil feed water tower having by-paths arranged to cut the same out in case of necessity.

The electric lighting plant, which is large enough for a town, was installed by the Thomson-Houston Electric company under the superintendence of its representative, Fred. A. Bowman, and the entire work was supervised by W. J. Hammer, consulting and supervising electrical engineer, who was retained as expert by the Palisades Amusement company.

A Simple Indicator.

The accompanying cut represents an indicating device which, though very simple in construction, may prove of



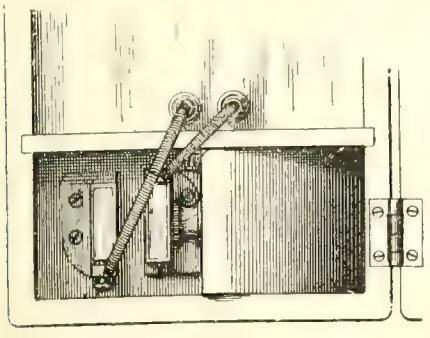
A SIMPLE INDICATOR.

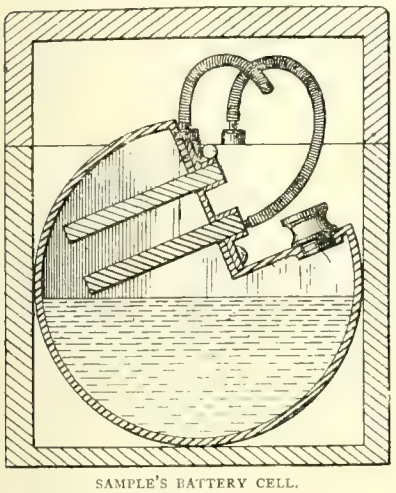
value in many instances. By means of a small mirror secured horizontally to the central pivot of an ammeter, the light of a lamp placed directly over it, is reflected on the ceiling, where numbers corresponding to those on the scale of the instrument are arranged. Thus the instrument, although inconveniently situated, may be read from any part of the room. The reflector must be secured in such a way as not to alter the balance, otherwise it may easily become a source of error. If the center of gravity of the reflector is exactly in line with the center of the pivots of the ammeter, as shown in the cut, the accuracy of the ammeter will not be practically affected.

The arrangement may be fitted to any electrical instrument, though of course it would have to be arranged to suit the special design of the instrument upon which it is to be used. This apparatus was devised and put into practice by Fred. W. Salmon.

Sample's Battery Cell.

The cut illustrates an improved battery cell designed especially for use in connection with portable induction coil outfits. The cell is circular in form, and is made of vulcanized rubber. The valuable feature of the arrangement, as will be readily appreciated after a glance at the



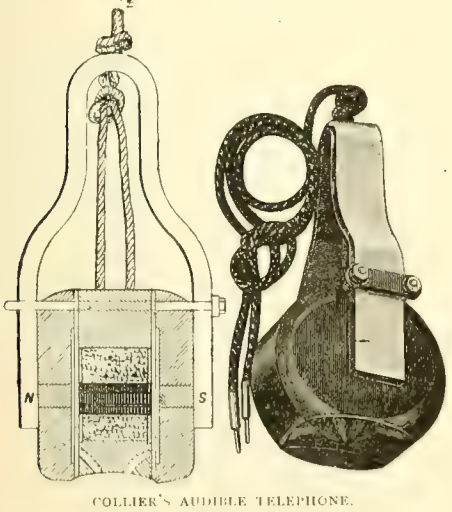


SAMPLE'S BATTERY CELL.

cut, is the roller-like form of the cell. By this construction a battery is provided in which one simple movement of the cell in its receptacle is all that is necessary to immerse the elements in the liquid. The battery is the invention of H. C. Sample of Ravenswood, Ill.

Collier's Audible Telephone.

If the statements in the London *Electrical Engineer*, from which the accompanying cuts are taken, are correct, the new Australian telephone illustrated herewith marks a distinct step in advance in the science of telephony. It is the invention of Rev. Arthur T. Collier, a Congregational minister residing in Australia, who became greatly interested in electrical and mechanical work. Mr. Collier is



COLLIER'S AUDIBLE TELEPHONE.

now living in London, where a company has been formed to exploit his invention.

The claim made for this telephone is that the sensitiveness of the receiver is increased to such an extent that the sound from it during an ordinary conversation is almost sufficient to fill a small room. Indeed, it is asserted that, compared with the efficiency of an ordinary Bell receiver, the sound from the Collier is as a person shouting, to a whisper.

The telephone itself embodies two simple ideas. These are the employment of a soft iron armature placed directly between the poles of the magnet, thus using two poles, and together with this two vibrating diaphragms—one between each pole and the core—and the method of taking the sound of the vibration from inside the diaphragm box instead of outside, as is now usually done. This latter arrangement in itself gives a greater volume of sound, it is claimed, by reason both of the greater activity of the magnetization and also from the additional magnetic variations that go on in the core—effects that have been already noticed, but not used. By combining these ideas and using two diaphragms the telephone receiver, it is asserted, is rendered far more sensitive, and its sound very much louder and more distinct.

The construction of the instrument can be seen in the detail drawings. The core of soft iron, laminated both end and lengthwise, is mounted on an insulating reel, and wound with wire. It is then mounted into a solid block of ebonite, having a ring turned out, as usual, to grip the metal diaphragm. On either side is a pole-piece, the two forming the poles of the magnet, each nearly touching the diaphragm. The magnet itself is placed outside the whole, its poles inclosing the diaphragms in a strong magnetic field. From the inside surface of the two diaphragms three small holes are led up each side to the mouthpiece of the telephone. This mouthpiece has a small cone, as shown, to lead and concentrate the sound into the ear.

One curious claim made for the Collier telephone is the statement that the difficulty with the telephones in India—that the natives of one caste will not use an instrument connected with another placed against the ear of a native of another caste—is now obviated, as it is not necessary to place the telephone close to the ear in order to hear speech-

Electric Percussion Drills at Last Chance Mine, Idaho.

In the accompanying cut is illustrated an electric percussion drill manufactured by the Edison General Electric

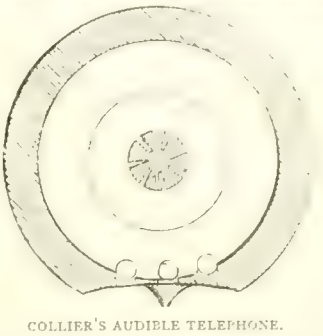
ELECTRIC PERCUSSION DRILL LAST CHANCE MINE, IDAHO.

company, and installed at Last Chance Mine, Idaho. Formerly air drills were used at this mine, but the superiority of the electric drill was so manifest when trial was made that the air drills were discarded for those of the type illustrated. It is reported that two air drills at this mine required five cords of wood for 24 hours, while four electric drills used only one and one-half cords, yet each

consequence of this evident superiority of the electric drill [illegible] air drill.

Growth of Electric Light Plants Operated by Gas Companies.

A significant indication of the [illegible] the increase in the number of gas companies operating electric plants [illegible]



COLLIER'S AUDIBLE TELEPHONE.

a statement of the rate of increase since October 1, 1888. At that time there were 153 companies operating 12,834 arc lights of thirteen different systems. In Brown's 'Directory of American Gas Companies" for 1889 another list was given, which showed that the number of companies which had added electric light plants to their works had almost doubled. The table demonstrated that 266 companies were operating a total of 21,313 arc lights and 55,890 incandescents, while the number of systems employed was 21. From the same authority it is found that the following year the number of companies steadily increased, 38 companies having added plants while two more systems were represented; the total was 304 companies, operating 23 systems, comprising 31,558 arc lights and 132,771 incandescents. Again, taking Brown's Directory for 1891, which has just been published, it will be seen that there has been no cessation to the adoption of plants by the gas companies, as the number has been increased to 317, while the number of systems operated is 24. A total of 42,022 arc lights and 221,411 incandescents are in use. It will thus be seen that in three years the number of arc lights operated has more than doubled, while nearly four times as many incandescents are employed as in 1888.

[illegible] been approved and the interurban electric line has been de-

[illegible] stance is cited in our Pittsburg letter. One electric rail-

lated upon the excellent street car service these figures prove the local companies give. Surely there is good cause for the popularity of electric railways.

THE end is not yet. Another novel application of the electric current has been devised. For over a year the "dear public" has read with morbid delight the tales of electricity's terrible dangers with which the daily press has seen fit to regale us. The accounts of the recent secret experiments at Sing Sing can also be referred to as being hardly conducive to a timid mortal's peace of mind. It is with a sense of relief, then, that we present to the readers of the WESTERN ELECTRICIAN a description of an invention "deadly" perhaps in a sense, but nevertheless, paradoxical as it may seem, one which some might consider a boon. It has been the lot of a Kansas man to do the work. Calling electricity to his aid, he enters death's habitation and long suffering humanity is given its last chance to regain the foothold seemingly lost forever. The field for this device, we think the reader will concede, is a large one, but it may be presumed that the inventor will meet with some difficulty in obtaining wiremen.

CANADA seems to be awakening to the importance of pushing ahead electrical enterprises. The leading feature of the International exposition this year at St. John, N. B., will be the electrical display. Elaborate preparations are being made for the event, and the leading electrical companies of this country have been invited to make displays. The exposition last year stimulated the local electrical interests and it is promised that visitors this year will find that the city has profited by the experience gained at the last exhibition. Electric lighting is making rapid strides in the Dominion and electric railways are beginning to loom up. At Quebec recently the mining engineers gave a large portion of their time to the application of electricity to mining, and good results are anticipated. Already there are signs of increased interest in this department. The convention at Montreal will no doubt do much to promote the interests of the electrical industries of the Dominion, as it will attract the representatives of all departments of electrical activity in this country.

THE WESTERN ELECTRICIAN does not aspire to be considered as an expert in matters pertaining to electrical executions. Neither does it desire to harrow the feelings and excite the disgust of its readers by recounting again and again the story of the recent secret proceedings at Sing Sing. It cannot forbear, though, to call attention to what is considered a most flagrant instance of neglect on the part of the alleged experts in charge of the inquisitorial proceedings. Those who have carefully perused the accounts of the executions cannot, we think, fail to be struck with the fact that the victims were burned. As we said above, we would prefer to say no more about "smoking electrodes," "burnt flesh," etc., but it does seem singular that the "scientific" gentlemen in charge could not have devised an electrode which would carry the current and remain moist for, say, less than a minute. One would think, judging from the information obtainable, that a bright school boy well up in physics might be able to construct such an electrode. We must decline to do more than point out what seems an unpardonable instance of neglect, or perhaps ignorance. If we are to have electrocution; if the public, in its usual state of blissful blindness to all things which do not affect the majority, sees fit to subject criminals to the experiments of men proficient, perhaps, in all else except this particular work—in the name of humanity let an electrical engineer be consulted, and an efficient method of making contact be devised.

As time goes on the justice of the strenuous opposition made to the electrical building of the World's Columbian Exposition on account of insufficient size becomes more and more apparent. Chief Barrett already sees clearly, from the applications now in hand, that the space at his disposal will be entirely inadequate to the demand made upon it, and is cudgeling his brains to devise an equitable arrangement whereby all exhibitors desiring to make displays in the electrical building can, in some measure, be accommodated. This will be a difficult task, and it is, to say the least, a great pity that the stupidity and stubbornness of the Construction Department, after the defect had been pointed out, made such a parsimony of space necessary. The members of the electrical fraternity have all along regarded the exposition with the greatest friendliness [illegible] intending to make their department completely representative of the very conspicuous position now occupied by electricity in so many avenues of human endeavor; but here is their ardor dampened at the outset. [illegible] remains have been sacrificed to the arbitrary decree of the architect placed at the head of the Department of Construction. This is perhaps a threshing of old straw, and undoubtedly the plans for the structure can not now be changed, operations having been begun for the construction of the building. But is it too late to provide for an electrical annex? The objection will at once be made that the arrangement of the grounds is such that no unoccupied space is left contiguous to the building now contracted for. But why cannot this design be slightly modified? For instance, what is to prevent a portion of the ground north of the site of the electrical building, now set aside for the "wooded island," being used as the site of an additional building? This annex could be on the north side of the lagoon, connected with the main building by a suitable bridge, or the course of the waterway could be changed so as to permit of the erection of the building immediately adjacent to the present site. The "island" is to be devoted entirely to purposes of recreation, and it would seem as though from its acres of extent enough space could be spared for the necessary building. It seems incredible that some provision of this sort could not be made if the Construction Department went at the matter in earnest. We commend the suggestion to the exposition authorities, assuring them that while the electrical people will make an important and attractive exhibit in any event, their enthusiasm and efforts will be vastly increased if an honest endeavor is made to make amends for the affront put upon them.

FOUR men were executed at Sing Sing, New York, by electricity July 7. The details of the proceeding have been shrouded in mystery, owing to the action of the warden of the prison, who pledged the witnesses to secrecy. There is a strong probability, however, that the veil will be removed, and the public informed of what took place in the execution room. It will be remembered that the Kemmler execution was so badly managed that some of the witnesses were overcome by the revolting spectacle. Public indignation was freely expressed through the newspapers, and there was a strong demand for the repeal of the law. The warden at Sing Sing, evidently fearing a repetition of the scenes at Auburn, took advantage of an unconstitutional provision of the law, and selected a jury of persons who were interested in promoting a favorable opinion of the new method. Not content with this, he required each of the witnesses to pledge themselves under oath not to tell anything that was unfavorable about the proceedings. Furthermore, armed guards were stationed about the walls of the prison to prevent newspaper reporters from gaining any information. Despite these precautions the outlook for a complete exposure of the proceedings is promising. The body of one of the murderers, Harris A. Smiler, was demanded by his wife, and taken to New York for burial. There an examination proved that the body had been burned, and further investigation showed that the doctors had not made a complete autopsy.

This proved sufficient to arouse public indignation, and the daily papers severely criticized all connected with the execution. In their defense the statement was made that after "instantaneous death" the current was again turned on "for the purpose of stopping the muscular action of the heart and lungs."

It was this admission that gave the opponents of the law the desired opportunity. Roger M. Sherman, an eminent New York attorney, who was interested in the proceedings to prevent the adoption of electricity as a means of capital punishment, called upon the coroner to make an investigation. He pointed out that the law had been violated according to the statement of the witnesses. "The repetition of the current upon any pretence," he says, "is in direct conflict with the statute, which requires that it shall be continued until death." Mr. Sherman insists that it is the duty of the coroner to make a thorough investigation of the affair, and require a full statement under oath from every witness of the executions. It is evident, according to his interpretation of the law, that if Smiler was killed in defiance of the statute; if, in other words, the plain prescription of the statute requiring a continued current was found inadequate, and was supplemented by repeated shocks, the death was not lawfully inflicted.

The action of the warden in attempting to prevent disclosures has had another effect. The press of the state condemns the secrecy, and most of the influential papers have pledged themselves to support no candidate for the legislature at the next election who will not pledge himself to work and vote for the repeal of the provision prohibiting the publication of details of executions.

Thus the matter stands. The mystery attending these executions has had the effect of raising grave doubts in the public mind as to the wisdom of the change in the mode of execution, and a repeal of the objectionable statute would not be surprising.

Cuadros' Apparatus for Automatically-Regulating the Firing of Ordnance on Ships.

In firing ordnance on board ship precision is very difficult to accomplish on account of the instability of the vessel. The least shifting of the center of gravity results

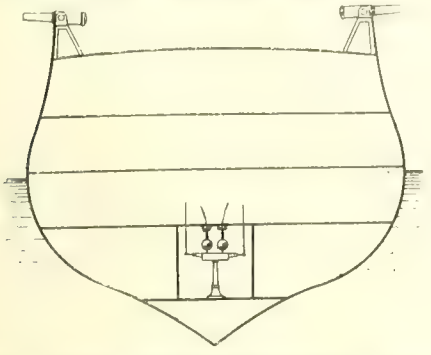

FIG. 1. CUADROS' APPARATUS FOR AUTOMATICALLY REGULATING THE FIRING OF ORDNANCE ON SHIPS.

in a modification of the angle of firing, and in consequence few projectiles are discharged exactly as desired. The cuts illustrate an arrangement devised by M. J. Cuadros of Liege, Belgium, for the purpose of overcoming the objection referred to by providing means whereby the gun is discharged when it is in the determined angle for firing.

An inspection of Fig. 1 will enable the reader to under-

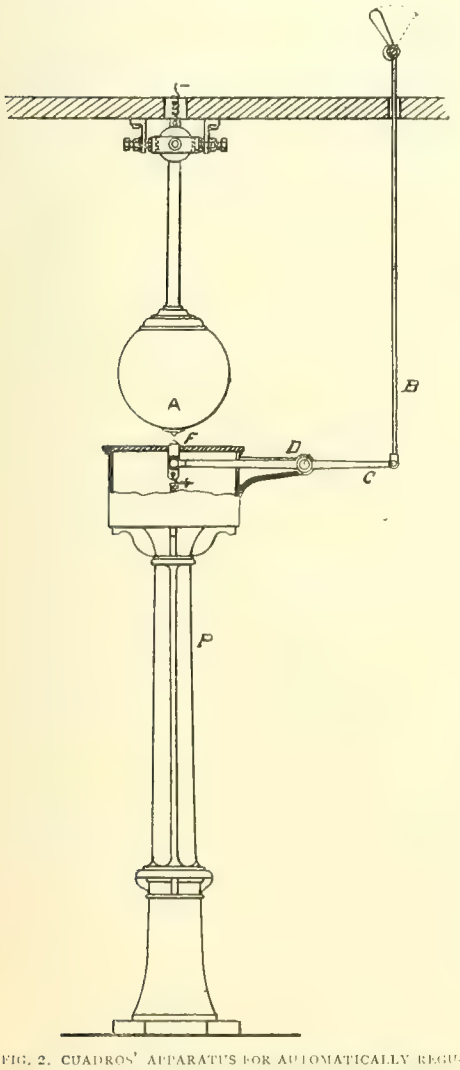

FIG. 2. CUADROS' APPARATUS FOR AUTOMATICALLY REGULATING THE FIRING OF ORDNANCE ON SHIPS.

stand the construction and operation of Mr. Cuadros' mechanism.

A is a pendulum suspended below the deck through the medium of a universal joint. An upright post *F* is rigidly fixed to a part of the vessel, and its upper end is provided with a boxing and bracket, to which latter is pivoted, as at *D*, a lever *C*. This lever is connected at one extremity with a vertical rod *B* and at its opposite end with a contact pin *E*. The contact pin is movable vertically through the top plate of the boxing and is connected with one pole of an electric battery. The pendulum *A* is connected with the other pole of the battery, which in practice is attached to fire the gun when a contact is made between the pendulum and pin. The rod *B* extends up through the deck of the vessel and is attached at the upper end to a handle as indicated.

The operation of the rigging may now be explained. The post and its contact pin *F* necessarily follow all the movements of the vessel, and when the vessel is in its normal position the contact pin is directly under the tip of the pendulum. If at this instant the circuit is closed, by raising the pin by a movement of handle *H* the gun is fired at the precise moment when it is at the desired angle of firing. It will be obvious that when the vessel is in its normal position the axis of the gun will be in the determined angle for firing, but in all other positions of the boat the angle chosen for firing is changed, and although the pendulum remains perpendicular it does not come in contact with the pin *E* unless the latter be raised.

Fig. 2 shows the device in position on a vessel.

Thomson's Method of Securing Metal Bands on Wooden and Other Articles.

In applying metal hoops to pails, kegs and similar articles, the usual practice has been to weld the ends of the band to form the ring, and to slip it when completed on the article.

Prof. Thomson's improvement consists in applying the band and welding it after it is in place on the article.

The cut shows a pail having three grooves into which the bands are to be welded. In the figure to the right the hoops are shown in place and welded.

The apparatus for welding is of the construction indicated below. *A* and *B* are two curved pieces of metal

THOMSON'S METHOD OF SECURING METAL BANDS ON WOODEN AND OTHER ARTICLES.

adapted to encircle the band and hold it in place upon the object during the welding operation. These two pieces are hinged as shown, and are insulated from one another at that point as indicated. The pieces carry the electrodes, which are simply two blocks of metal adapted to bear upon the ends of the band after it is in place. The blocks themselves are connected with the generator. The two curved pieces are lined with insulating material to avoid electrical contact with the band, excepting at the electrodes.

By this method of welding the band may be seated in a groove so that it cannot possibly fall off. This method is of especial value in the case of pails, barrels, or such articles which often fall to pieces owing to shrinkage, which lets the retaining band drop off. It is also of evident importance in the case of tool handles, such as the handles of chisels or similar instruments which require a retaining band, in order that splitting of the wood of the handle may be prevented.

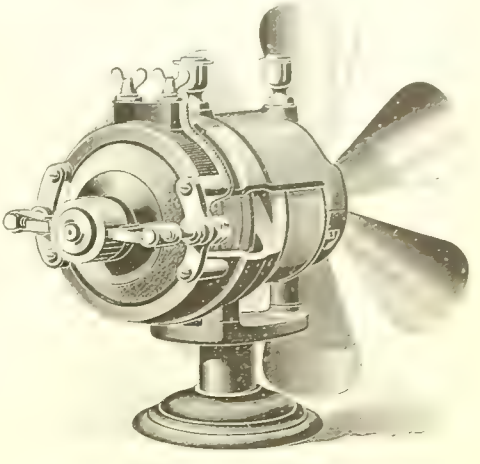
New C. & C. Fan Motor.

The great increase in street railway and other power circuits of a pressure of 500 volts has recently led to a demand for small motors and fan outfits adapted to this voltage.

The problem of designing a $\frac{1}{8}$ or $\frac{1}{4}$ horse power motor for so high a voltage has many factors that do not occur in building larger machines, while some of the main objects to be attained in large machines assume a very different aspect in these smaller sizes. The motor herewith illustrated was designed for 500 volt circuits by F. V. Henshaw of the C. & C. Electric Motor company, New York.

The field magnet is semi-ironclad, being formed of two castings joined at one end and held by a single bolt, while

passes through it, having bearings at each end. As will be seen, this arrangement allows a relatively large diameter of armature without increasing the size of the machine greatly. The armature is of the ring type supported on the shaft by three arms. [illegible]



NEW C. & C. FAN MOTOR.

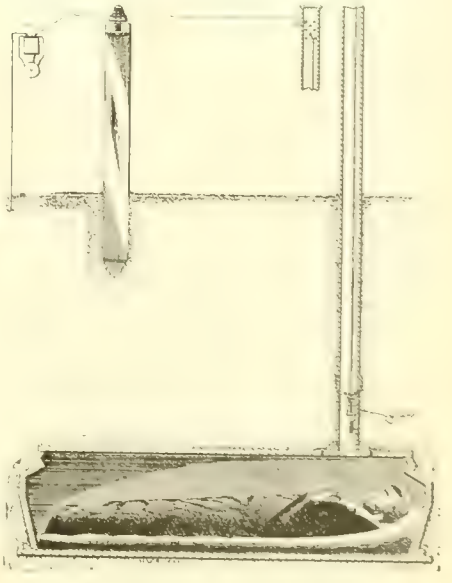
tator is fastened. This disk serves to keep the frail connecting wires in place and also as a protection to the armature. The brush-holders carry two or more round carbons of standard size, which can be replaced by simply turning the holder around, putting in new pieces, and turning back. Both field and armature coils are wound separately on a lathe. With duplicate sets of armatures and field bobbins of the proper winding it is but the work of a few minutes to change these machines from one voltage to another, which is sometimes convenient.

The $\frac{1}{8}$ horse power motors are finished with bearings requiring very little oil, while the larger motors have self oiling bearings.

The C. & C. Electric Motor company of New York is introducing these machines.

An Electrical Grave-Annunciator.

Electricity has been applied to so many things that we are prepared for almost any use of it, no matter how strange. An Illinois man has patented an electrical tooth extractor; a New York man advertises an electrical pad as a universal panacea; but it has remained for a Kansas man to



AN ELECTRICAL GRAVE-ANNUNCIATOR.

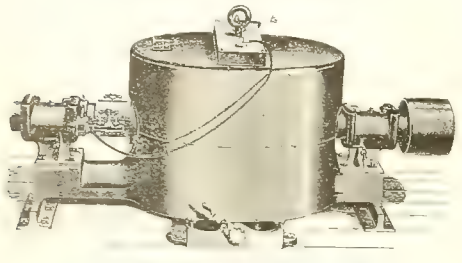
apply it in a device which can literally "raise a man from the grave."

The accompanying cut will show at a glance the purpose and working of the appliance. Supposing the corpse to be a live one, to use a paradoxical phrase, its first action would naturally be to move the hand. As can be readily seen, its first movement will close the circuit and give the signal at the annunciator above. The inventor of this new life preserver, or life detector as [illegible] of Topeka, Kan.

The Mayo System.

The Rockford Electric Works have just completed a new dynamo and motor, the invention of Geo. A. Mayo, the electrician of the company. The dynamo is compound wound, and it is claimed that perfect regulation has been reached, and that no rheostat or resistances of any kind are used.

The new motor has a cast iron shell entirely inclosing



THE MAYO SYSTEM.—IRON CLAD MOTOR.

the field magnets and armature to prevent magnetic leakage, making it possible, it is claimed to use all the lines of force. These motors are to be known as the "iron clad" and are made in size from one-half to sixty horse power. They are provided with self-feeding carbon brushes, self oiling boxes, and other novel details that will undoubtedly materially assist in their introduction.

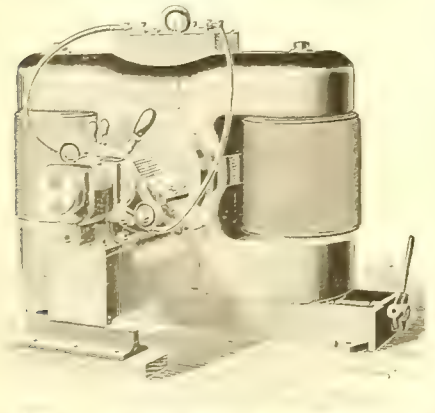
A specialty is being made of isolated plants, several now being under contract. The *Chicago Tribune* is using three motors of this pattern, one of 40 horse power and two of 15 each.

New Line Tools.

The tools shown herewith are manufactured by Mathias Klein & Son, 87 and 89 W. Van Buren street, Chicago. The Havens patent steel eccentric clamp is specially adapted for use on iron wire and is made in two sizes for light and heavy work. The Klein clamp is designed for stretching hard drawn copper wire, the wire being held between two flat brass jaws which open and close automatically. The jaws have a long flat grip, and it is claimed will hold the wire without the least danger of bruising or kinking. The steel tie wrench is also designed for use on hard drawn copper wire and has been adopted by the Western Union to the exclusion of all other tools of this class. The loops or ears are put in so that a tie can be made close to the insulator, and it is claimed the wrench is specially suited to this purpose, or in making splices. The tools have just been brought out and are made of the best steel.

Faraday's Religious Life.

Some curious reminiscences of Faraday are given in the *Referee*, an English publication, by G. R. Sims It seems that the present Mr. Sims and his father knew the eminent scientist in a peculiar way. They were of the persuasion known as Sandemanian, and worshiped in a little court off Aldersgate street. The Sandemanians were Bible Christians, and their faith was simple and primitive in the extreme Michael Faraday was an elder of this chapel, with a butcher, a gasfitter and a linendraper. In

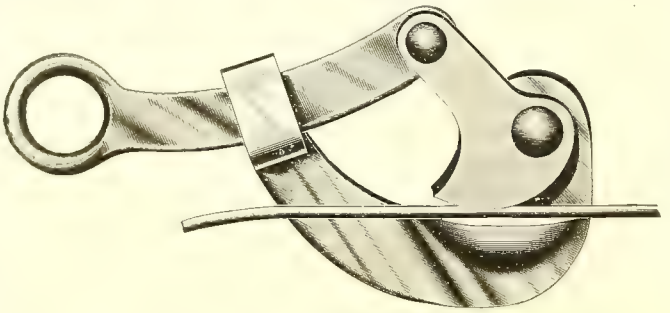


and a blessed peace fell on the little meeting-house. Faraday Mr. Sims remembers best as an elder, though he often met him at the elder Mr. Sims' house at Peckham. He had a very winning way with children, and they all liked him. The Sandemanians liked him very much as a man, but they preferred the butcher as a preacher, and they considered it a terrible thing for a good man to devote himself to such doubtful subjects as electricity, instead of reading the Bible and being satisfied with things as they were.

Proposed Electric Road from Jersey City to Newark.

Gradually electric lines are spreading in the environs of New York, and in time they can be relied upon to dissipate the distorted and senseless idea now seeming to pervade the minds of the people of that city in relation to electric traction. Newark has two electric railroads, which have been in operation nearly a year. Jersey City has another, which in the short time it has been running has demonstrated its practicability. Now there is a scheme on foot to join Jersey City's road with those in Newark, and to run electric cars from the ferry to Irvington and Orange. The route laid down is the old plank road, which belongs to the Pennsylvania railroad. It is proposed to lay tracks out through Marion and across the meadows through about three and a half miles of waste land, from which no profitable traffic can be expected for many years. At each end of the projected line there is a large population, and it is believed that the road will pay well from the start.

C. B. Thurston of Jersey City, president of the Newark Plank Road company, one of the few toll roads still existing in the vicinity of New York, and also president of the Jersey City and Bergen railway, says that the electric railroad project is to go through. It is proposed to lay tracks upon each side of the plank roadway, with an overhead trolley construction. In the cities the cars can run at ten or twelve miles an hour, and across the meadows the speed may be accelerated to twenty-five or thirty miles without danger. The fare will probably be 5 cents anywhere in Hudson county and 10 cents to any part of Newark or its suburbs, including ferry tolls. The present rate of fare on any of the steam roads is 15 cents straight, or 25 cents for an excursion ticket, with monthly ticket rates of 10 cents. The scheme involves the consolidation of the interests of four corporations.



NEW LINE TOOLS.—STEEL ECCENTRIC CLAMP.

The Electrical Executions.

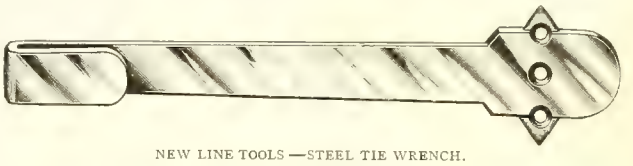
The execution of four murderers at Sing Sing last week under the electrical execution law was announced in the WESTERN ELECTRICIAN, but as the executions took place too late for an extended notice only a brief statement of the fact was made. Although the witnesses were sworn to secresy, some facts have become known which indicate that the horrors of the Kemmler tragedy were not entirely absent from the execution at Sing Sing last week. It was at first announced that the executions had been eminently satisfactory, and that there had been no hitch in the proceedings, but when the body of Smiler reached New York it was found that the face had been burned, and the undertaker added that the calf of the leg on which the electrode was bound showed plainly that it too had been burned. According to the press dispatches, "The eyes were sunken so far into their sockets as to cause many of those who saw them to exclaim that they had been burned out. When the tightly closed lids were raised the burned flesh was displaced. On each cheek there was a large blister. The hair and mustache had been carefully trimmed where they had been singed."

Drs. Ward and McDonald, who witnessed the execution, at first stated that everything had passed off satisfactorily but when the statement concerning the burning of Smiler's body was shown them they did not deny it. Furthermore, they admitted that the current was turned on twice, and that on one occasion the electrodes burned out and the flesh of the victim was roasted.

One of the clergymen who attended the murderers is quoted as saying that when the whole story was disclosed it would be found that all of the men were burned.

The fact that the warden undertook to withhold all details of the execution from the newspapers, and that in order to do this he stationed armed guards about the prison [illegible] executions commented upon by the daily papers of New York. It is assumed that the provision of the law prohibiting the publishing of details of the execution is unconstitutional, and the daily papers, as a matter of course, are prepared to fight it. The *Sun* has led the way by announcing its intention of supporting only such candidates for the legislature who will pledge themselves to repeal the obnoxious law. This opposition is not confined to the metropolis, but is pretty generally echoed throughout the state. A very sensible review of the situation appeared in the Rochester *Post-Express* the day of the execution. It is herewith appended:

"The law for electric execution was passed because the public conscience revolted from the brutality of hanging. It was passed on the theory that killing by electricity would be quick, certain, painless, and unsensational. If it does not serve the purpose for which it was passed it should be



NEW LINE TOOLS.—STEEL TIE WRENCH.

repealed. The provision as to secresy, if carried out, would prevent the public from ever learning the actual facts; and leaving the public conscience, which is the ultimate sanction for the law, unenlightened.

"We know that the first electric execution was a horror; those that took place yesterday may have been worse or better. The presumption to be drawn from secresy is that there was something dishonorable or horrible to hide.

"It has been our opinion steadily that the people of the state of New York ought to know that their condemned murderers are actually executed, and ought to know how they are executed. Otherwise the people of the state of New York have no right to provide for the trial and conviction of murderers. We cannot put aside an iota of responsibility in this awful business of avenging a human life. We cannot turn over a criminal to star-chamber processes and to the secret manipulations of professional charlatans.

"We argued last year for the amendment of this electric execution law. We say now that no man should be chosen to the legislature who is not ready to move for its amendment. It bears on the face of it an insult to the press and a menace to free discussion; and no newspaper of either party should consent to support a candidate who means to defend it.

"It must be always, as it stands, a source of suspicion and sensationalism at least, and may be the source of worse things.

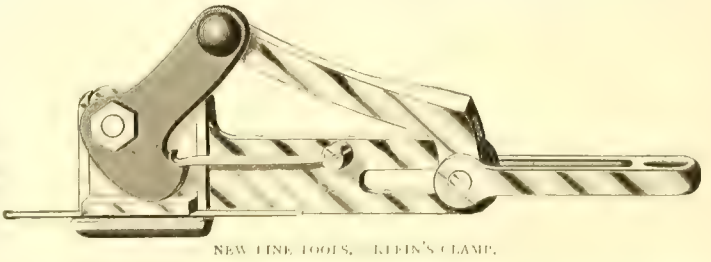
"In the meanwhile the people of the state of New York remain in beautiful uncertainty as to whether they are to consider themselves as philanthropists or brutes—with the strong probabilities in favor of the brutality horn of the dilemma.

"Suspicion and sensationalism have full swing; and an old-fashioned hanging begins to seem like a steady-going and reposeful pastime."

There is a strong probability that some of the witnesses of the Sing Sing prison tragedy will be put in an embarrassing position in regard to their promises to Warden Brown not to reveal the details of the tragedy. Coroner Levy, upon reading Roger M. Sherman's letter on the legal questions involved declared his belief in its statements and his intention to follow the course they suggested. The grounds given in the letter for a coroner's intervention were allegations that the law was violated by a repetition of the electric shocks, and that it was the duty of a New York coroner to hold an inquest on the death of Smiler, he having been buried in New York county. "This is what I propose to do," said Coroner Levy, "and I shall subpœna all those who saw the execution and over whom I have jurisdiction. They will be made to tell the things that went on in that death room to a jury who will know the difference between reflex action and respiration—a jury of prominent and intelligent citizens."

If the coroner can carry out his plan, the facts in regard to the execution will be brought out under oath, and, under the absurd provisions of the law as it stands, no newspaper can publish the proceedings of the coroner's jury without the commission of a misdemeanor.

Warden Brown announces that he will not submit to



NEW LINE TOOLS.—KLEIN'S CLAMP.

Coroner Levy's authority unless compelled to do so; and altogether this business of secret execution will probably be the result of endless discussion and a series of sensations.

The Western Union Telegraph company has placed new furniture of the latest antique oak pattern in its receiving department at Toledo, O. New floors, new ceiling of corrugated iron and incandescent lights are among the improvements noted.

The Electro-Magnet in Eye-Surgery.[1]

By Silvanus P. Thompson and J. Latham Thompson

For many years past ophthalmic surgeons have used both steel magnets and electro-magnets. Indeed, the use of the loadstone has been known for two centuries,[2] for the purpose of extracting from the eye-ball chips of iron which have by accident lodged therein, as frequently happens in engineering workshops to fitters and metal turners. Later, in 1745, Dr. Milnes, in his "Observations of Medicine and Surgery," describes how he applied a loadstone to remove a piece of iron from the iris. Probably this was not strictly the case, as he says, "Immediately it jumped out." It is more likely that he meant that the fragment of iron was embedded in the cornea in front of the iris. According to Hirschberg,[3] Dr. Meyer of Minden was, in 1842, the first to use a magnet in extracting fragments of metal from the actual interior of the eyeball.

In the middle of this century cases of successful removal were recorded by Critchett,[4] Dixon, White, Cooper and others. There seems to have been little advance until 1874, when Dr. McKeown of Belfast recorded in the *British Medical Journal* several successful cases treated by means of a permanent steel magnet tapered at each end to facilitate its introduction.

In 1880 Gruening of New York employed a permanent steel magnet composed of a number of "cylinders" (*sic*), united at each end and fitted at one extremity with a needle-shaped pole.

The first use of the electro-magnet in this connection is accredited to Hirschberg of Berlin in 1877.

In this country Snell[5] of Sheffield has been the chief advocate of its use, and in his hands splendid results have been obtained. In the *British Medical Journals* for 1881 he describes his instrument and records the result of several operations. His experiments have steadily progressed since then, and in a recent number of the same journal he brings up the number of his recorded cases to 77.

The thing needed for this special service is an electro-magnet which can be fitted with polar appliances of various elongated forms which can be introduced into the wound in the eyeball to a sufficient distance to enable the particle of iron to be attracted and withdrawn. It is necessary at the same time that the electro-magnet should not be too heavy to be conveniently held in the hand of the operating surgeon, and that it should be capable of being excited with current from a battery of moderate size, such as an oculist might be expected to be able to manage and maintain without having to call in a skilled electrician at every occasion of its use. It is obvious that, other things being equal, a magnet of considerable projective power is desirable; hence one with a long core or with an iron expansion at the posterior end of its core, is preferable to a short one. Possibly in some cases the placing of a mass of iron behind the patient's head during the operation might aid the electro-magnet to project its magnetic field to the desired depth. Various forms of magnets have been devised by various experimenters

Snell's instrument, which may be quoted as the typical form commonly used by ophthalmic surgeons in this country, consists of a soft iron core surrounded by a coil of insulated copper wire inclosed in an ebonite case. At the one extremity are the terminals for the battery connections, and at the other the soft iron core is tapped to receive the variously shaped and sized needle poles. He recommends the use of a single quart bichromate cell to generate the current.

Hirschberg's instrument consists of a hollow cylindrical core with two curved pointed poles of different thickness for external and internal use.

Bradford of Boston devised an instrument almost identical with Snell's, and simultaneously with the latter. It is, however, a much heavier and more powerful agent.

McHardy of King's College Hospital used a very similar instrument, but of much reduced size and weight.

The latest form, shown in the cut, is that brought out by Tatham Thompson of Cardiff, and is a further modification of Snell's instrument, but for the same weight and bulk additional power is claimed, as the magnetic circuit is perfected by means of a collar of iron continuous with the core projecting forward over the insulated coil toward the manipulative pole piece.

The core is tapped at its extremity to receive the differently shaped poles or an intermediate polar extension where deeper probing is required. The battery used with this consists of one or more quart bichromate "dip" cells. This instrument is shown in the illustration in its actual size, and its weight is only about five ounces.

The most frequent use of the instrument is in removing fragments of steel or iron from the surface or embedded in the coats of the eye, and by its use much disturbance and laceration of the delicate structures is avoided, which the older methods of cutting out or withdrawing by means of forceps, spuds, or curettes too often involved. Its most valued properties are, however, best demonstrated where it is used for the removal of foreign bodies which have penetrated the walls of the eye. It is not too much to say that in many cases it has been the only possible means of preserving sight.[6]

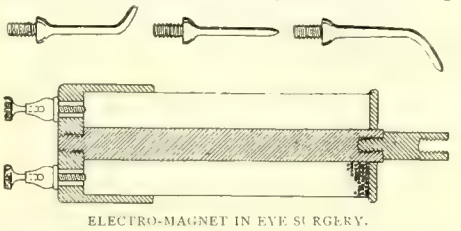
In the first place, it is of diagnostic value, for where a fragment, for instance, has perforated the cornea or anterior transparent part of the eye, it can often be proved whether it is steel or iron by observing whether it is acted on by the close approach of the instrument. If no movement is observed, and no peculiar sensation of dragging pain felt by the patient on the approach of the magnet, it may be due either to its not being a magnetizable metal or to its being gripped by the tissues, or encysted with inflammatory material thrown out by its irritating presence. If in this case a very lightly suspended needle be magnetized and held close to the eye, it may sometimes be found to dip toward the foreign body. If it should chance to be a steel fragment, this effect is greatly increased by holding the electro-magnet close to the eye for a time, so as to magnetize the offending particle.

Further still, the instrument is at times of immense use in moving the fragment from one part of the eye where it is inaccessible, and dropping it in a more favorable position for subsequent removal. For instance, suppose the fragment of steel or iron has penetrated the cornea and lodged in the crystalline lens, it has happened in several cases that by applying the electromagnet to the cornea the metal has been attracted forward through the lens substance, across the aqueous humor contained in the outer chamber of the eye and then dropped by opening the circuit on to the floor of the outer chamber; then a small opening being made at the most dependent part, the pole of the instrument introduced there, and the fragment readily removed.

In at least one recorded case a sharp-pointed fragment, which had penetrated deep into the lens, has been seen to force its way forward through the lens substance and lens capsule, through the iris, and actually be drawn through the cornea, and so removed completely without involving any cutting operation whatever.

It is, however, in those cases where the foreign body has penetrated the posterior or vitreous chamber of the eye that the wonderful results obtained by the electro magnet are best seen. Where only the outer chamber or the lens is the seat of the mischief, other means may possibly succeed; but when a fragment has penetrated the vitreous chamber, we require an instrument not to go blindly searching round, disturbing the delicate structures and risking the escape of the semi fluid contents, but one which will attract to itself the offending particle, and this is where the instrument which we are considering reaches its highest achievements.

Many successful cases have been recorded by Snell, Hirschberg, Lloyd Owen, McHardy and others of fragments of steel thus removed from eyes which otherwise must have inevitably been lost.



ELECTRO-MAGNET IN EYE SURGERY.

The most serious and desperate cases of all are where the metal has actually traversed the inner chamber of the eye and become embedded in the delicate retina and choroid lining the posterior wall. So far as can be ascertained only three successful cases of removal from this position have been recorded. The first by Galezowski, in 1882, where a fragment of iron had passed through cornea, iris and lens, and was lodged in the retina. Its position was noted by means of the ophthalmoscope, an instrument employed by ophthalmologists for examining the interior of the eye. An incision was made in the sclerotic or white coat of the eye over the situation, and the fragment removed by means of the electro-magnet. The second, was recorded by Hirschberg in 1888. The third was by Tatham Thompson of Cardiff in 1890. Some detailed account of this will illustrate the method of the procedure.

The patient was a blacksmith employed at one of the South Wales collieries, and on December 8, whilst "stamping" a new "pick," was struck on the left eye by a fragment of the new tool. The fragment struck him on the sclerotic or white of the eye, about a quarter of an inch from the margin of the cornea. He felt little pain at the time, but two days later dull pain supervened, and considerable irritation and dimness of vision, not only in the injured but in the sound eye.

He was sent to the Cardiff Infirmary on December 10. When examined there, a small wound was found at the point where the fragment had entered on the inner side, and on ophthalmoscopic examination, the piece of steel could be seen embedded in the retina at the upper and outer part. The track which it had made in traversing the vitreous chamber could also be distinguished by slight opacities in the humor. The uninjured eye showed distinct signs of sympathetic irritation. The next day the patient was put under the influence of ether, the wound of entrance slightly enlarged to allow the introduction of the pole of the electromagnet. This was passed across the vitreous chamber in as nearly as could be calculated the direction originally taken by the fragment. On withdrawing the first time nothing resulted, but at the second attempt the piece of steel came readily through the wound "in tow" of the pole. Only a very small bead of vitreous humor escaped, and the eye was dressed antiseptically and bandaged. At the end of 24 hours he could count fingers at four feet distance, was quite free from pain and dread of light, and the dimness of the other eye had largely disappeared. The wound healed in three days, and the sight steadily improved, till on December 30 he could read moderately sized print. Examined by means of the ophthalmoscope, the scar formed in the retina at the point where the fragment had lodged could be distinctly made out, as well as some patches of hemorrhage caused either by injury from impact of the fragment or by injury of retinal vessels at the time of its removal.

On January 13, 1891, he could read small print; his

[illegible]

general surgery for the removal of needles from the soft tissues of the body or limbs.

Construction and Operation of Cable and Electric Railway.

In the discussion on the construction and operation of cable and electric railways before the Engineers club of St. Louis the following remarks were made

W. H. [illegible] cost of power on cable and electric roads. The unfavorable results shown by one of the electric roads were attributed by the speaker largely to the fact that high speed engines belted direct were used, the inference being that if large slow speed engines with countershafting had been employed, the cost of the power would have been greatly reduced. I have not been able to secure any data bearing directly on this point, but there is much to be said in favor of the opposite view. Two years ago in a paper read before this club, I discussed this subject at some length. The conclusion which I reached then was, that for approximately constant loads, the large engines with shafting were preferable, but where the work varied largely, the high speed engines belted direct would be found more economical. I have taken every opportunity since then to study the question further and can see no reason for changing my view. The unfavorable results cited by Col. Meier, could, I think, be traced to other causes. The largest builders of electric roads have not yet reached a conclusion—one of them preferring large low speed engines with shafting and the other high speed engines. The practice of the latter company is based on experience gained in operating large incandescent electric light plants, where the load is subject to wide fluctuations, though not as sudden or severe of course as in railway work.

Compound high speed engines are, under similar conditions, at least as economical as the single cylinder Corliss engines, generally used. If however, we compare the latter with single cylinder high speed engines, the Corliss engines will probably show a saving of 15 to 20 per cent. in fuel. The large countershaft required with the low speed engines consumes a constant horse power—varying from about 10 per cent. of the maximum load, and 15 to 25 per cent. of the average load up to as much, or more than the useful output under light loads. It would appear, therefore, that the superior economy of the low speed engine is almost fully balanced by the excess of power lost in driving the shafting. A further advantage is that during those hours when the load is light, several of the small engines may be shut down, leaving the remaining engines to run at more economical points of cut off. The large engine, however, must run all the time together with most, if not all of the shafting. Under light loads, therefore, the large engine will cut off at a very early point in spite of the excessive dead load, while the smaller high speed engines would do only useful work, and under conditions far more favorable to economy. It would seem, therefore, that the net fuel economy for a whole day's run would be in favor of the high speed engines.

Closeness of regulation seems also to be in their favor. I was told yesterday that the variations in speed in a certain low speed station in this city are three times as much as in a corresponding high speed plant here. This is as might be expected for the changes of load are felt directly by the governor instead of having to be transmitted through the heavy shafting; besides which the engine itself has more than three times as many opportunities to adjust its speed in the same time.

The high speed permits the plant to be installed for the least first cost, and to occupy the least space. The necessary reserve engine also requires a much smaller investment of idle capital and space. These items affect the fixed charges seriously. An accident to one of the large engines is a serious matter, as it means a large reduction in the capacity of the station, while one of the smaller high speed engines could be spared almost without being missed, it being so small a part of the total capacity.

Electric railways have an advantage over cable lines in that the power station may be located at some distance from the line, thus getting the benefit of cheaper land, switching facilities for coal and ashes, cheap water—and sometimes water power. The cost of increased length of circuits, cost of maintenance, and losses due to leakage, drop, etc., must all be taken into consideration in determining how far away it will pay to go

Prof. Nipher: This discussion seems to me to be like an attempt to determine whether it costs more to support the family of a lawyer than a physician by an exhibit of the family bills of a dozen cases, selected by the champions of the two sides for the purpose of making a case.

I do not know of another industry that has grown in so short a time to such tremendous proportions, as the electric railway business has assumed in the last two years. It is certainly proper for those who oppose the system to work with diligence. The rapid growth has, however, brought some disadvantage. The manufacturing companies have not only been pushed to the utmost to fill orders, but they cannot find the men to properly install the plants they sell. It has, therefore, happened that men who might perhaps succeed in building a telegraph line, are sent to install a railway plant. The steam engine part of this plant has been given into the hands of some one who had an engine for sale.

Nothing has surprised me more than the large slow-speed engines and immense countershafts with which some of our power stations are adorned. To establish such a plant is to ignore the [illegible]

In the first place the countershaft at once wipes out the gain in efficiency which a large engine is supposed to

yield. It is again wiped out by uneconomical operation of the engine during the hours of light load.

Again, a large engine takes no notice of the distress of a single over-loaded dynamo. It is more difficult to make individual dynamos carry their proper share of the load. As is well known, when dynamos are working in parallel, if the potential of one falls three or four per cent. it ceases to act as a generator, and may even be driven as a motor. If it were a plain shunt dynamo, it would aid in driving the countershaft, but the other machines acting as generators would be overloaded, and a great loss of energy would be the result. The situation is then, that only part of the generators are sending current to the line, and they are dividing their current between the line and the dynamos which they are operating as motors.

But in the operation of a railroad, where great and sudden changes in load may occur, a compound dynamo might and probably does reverse and work against the engine in such a case. This is due to the self induction in the shunt coil, which causes the series coil to act first in case of a lagging dynamo.

Such experience has long ago been met in electric lighting, and the way of providing against it is well known. When the Edison central station was started in New York, they had separately driven dynamos. The engines used were in good standing, but they were finally thrown out because they were not well enough governed. Another engine was substituted, and it succeeded, and was given a great reputation as a well governed engine. It is now known that the first engine failed because it was a well-governed engine. If one or two dynamos began to carry the rest of the plant as well as the light, the engines maintained their speed until something gave way and the lights went out. The second engine placed under the same circumstances, slowed down and shifted an equitable share of its surplus load to the lagging dynamos.

In a cable system, if a load is suddenly thrown on, the shock on the engine is cushioned by the lifting of slack cable along the line. In an electric system, the change is instantly felt in the power house. The moving masses in the power house of an electric railway should be small, and the engines should be high speed engines not too well governed. To build an electric power plant in imitation of a cable plant, is to abandon some of the main advantages of an electrical system. Such plants, however, serve to aid us somewhat in the practical solution of a somewhat famous mechanical conundrum which interested men in a former age more than it does now,—what will happen if a body moving with resistless energy, collides with a body which cannot yield?

There are plenty of electric roads which are being operated in a most satisfactory way. We hear nothing of them. We need go no further than Kansas City to see a most impressive case, where five miles of electric road and five miles of cable road are being operated from the same station. They have the same number of cars, and the cars are worked to their full capacity. A mere inspection of those two plants will satisfy any person that a properly installed electric plant needs no defender when compared with a cable plant. When an electric road behaves like those of which we have heard to-night, you may be certain that there has been a mistake somewhere. And it takes time to educate the employes of an electric road. They now destroy a great deal of machinery, because like most people, they cannot learn from the experience of others, and cannot think quickly in new emergencies. Our cable friends should be patient, for there is every evidence that the electric road is here to stay.

Electricity Beneficial to Gas Interests.

[illegible] says: "In a circular recently issued to the shareholders of the Standard Gas Light company, New York, it is stated that President Andrews, at the last annual meeting asserted that statistics proved that the growth of gas consumption in New York City, for forty years prior to the introduction of electricity for lighting purposes, averaged about ten per cent. per annum. That is, the gas output doubled every ten years and that the city had doubled in population every seventeen years. Since the first introduction of the electric light, however, the increase in New York of the consumption of gas has been much more rapid. It almost im[illegible] per cent per annum, and in 1887 showed a growth equal to about 14 per cent. per annum, a ratio of growth that was still further exceeded in [illegible] was willing to stand [illegible] York was [illegible] one half years, [illegible] He thought one reason [illegible] due to the fact that the [illegible] eye to the aggre[illegible] that people are not [illegible] that formerly satisfied them. Again, a more luxurious mode of living is [illegible]

New Electric Railway System.

[illegible] London and other parts of England, so unqualified a success has the first been in [illegible] to [illegible] with [illegible] approval [illegible]

CORRESPONDENCE.

New York Notes.

NEW YORK, July 11.—The topic of the week is the quadruple electrocution at Sing Sing last week. There seems to be no shadow of a doubt that the electrocutions were this time successful. None of the hitches that occurred at Auburn in the Kemmler killing were repeated, and according to reports everything worked smoothly. Some of the daily papers praise the method and express their approval in such terms as these: "To-day New York may claim the proud distinction of leading the world in this feature of its penal system. It has not only substituted the electrical chair for the gallows but has proved the superiority of the former over the latter. * * * No doubt other states will follow the lead of New York in adopting the greatest reform of the century in criminal administration, and even Europe may study with advantage the reports of what took place on Tuesday morning within the prison walls on the banks of the Hudson. Electricity is destined to become the motor power of the world, and the means of illumination as it already is the agent of communication. Why should it not become in time the universal method of inflicting the death penalty?"

The *New York Herald*, so great was its enthusiasm over the subject, even went so far as to cause an autopsy to be made on the body of Smiler, which his widow was allowed to remove for burial. The autopsy showed that death was instantaneous and painless. The brain was found to be in an almost perfectly normal condition. The temples, with which the electrodes came in contact, were slightly disfigured but not even the eyebrows were singed and the delicate optic nerves were unimpaired. It appears that although an autopsy was made previously by the prison officials it was not complete as the brain was not opened. The *Herald* criticizes on the warden and physicians for this omission, in revenge for the muzzling that the press was subjected to, and declares that they were all guilty of misdemeanor, as the law requires a post mortem examination of the body of the convict immediately after the execution. A legal autopsy naturally includes an examination of the brain, and as this was only performed on one of the four bodies, according to the statements of the physicians themselves, the law was evidently violated.

The daily press was unanimous in condemning the secresy with which the executions were conducted, and a loud howl of indignation has gone up, the echoes of which have not yet died out. Warden Brown stationed armed guards in the road ouside the prison with orders to shoot any reporter who should step over the line he had marked as the limit to their zeal. He also pledged all the witnesses of the execution to secresy, and so he had the reporters entirely at a disadvantage. Consequently he has been the worst abused man in New York state this week, and his "star chamber proceedings" have been bitterly denounced in newspapers of all shades and classes. It would not be surprising if the efforts to maintain secresy were relaxed somewhat in future, in view of such general protests.

The *New York Times* recently had an interesting editorial on "Electricity and Vegetation" based on an article published a few weeks back in the WESTERN ELECTRICIAN in which were described numerous experiments made in France and in Finland to acertain the effect of electric currents on growing vegetation. In the editorial in question the results of such experiments are briefly summarized and this prophecy is made: "It may be that in the course of time the electric current will be used profitably by market gardeners, and in connection with hothouse culture."

The *Times* is a newspaper that shows a very healthy interest in scientific matters, and this week it published an interesting article in which the discussion on the proposed rapid transit scheme is very pointedly summed up. The underground electric system is indorsed as the "ideal rapid transit system for cities," and the objections to it are characterized as emanating from two main sources—from those who don't know and from those who won't know. The objectors chiefly state that the tunnel railway would be dim, stuffy and unwholesome, and that electric motors cannot do the work. The facts are that the tunnels and stations of the London line are well lighted and well ventilated, and there is absolutely no color as to the motor question no reader of an electrical journal needs to be told that [illegible] can be made of sufficient power to draw a [illegible] of four or five cars, but as well as they can [illegible] three cars. Several new lines on the Great [illegible] London and other parts of England, so unqualified a success has the first been in [illegible] to [illegible] with [illegible] approval [illegible]

The annual meeting of the New York Electrical society was held last night. The gain in members during the year has been large and the quality of papers read unusually good. A large number of the members are young men, students and employes of electrical companies, and the policy of the society is to secure practical papers on electrical applications and development rather than those dealing with theoretical questions. This plan of proceeding is heartily appreciated by the members and the attendance at meetings is always satisfactory in point of numbers. The action taken by the society in severing its connection with the American Institute has been generally indorsed by the members. Since the declaration of independence the society has undoubtedly gained in vigor and standing. Its financial condition is healthy, as the treasurer's report showed a handsome surplus over last year's expenses and there are no debts. The officers elected for the ensuing year are: President, F. B. Crocker; vice-presidents, T. C. Martin, E. L. Bradley, G. H. Stockbridge, C. Steinmetz, W. J. Hammer and F. J. Sprague. A committee of three, F. B. Crocker, George H. Guy and Herbert Laws Webb, was appointed to select a fixed meeting place for the society. The society will be officially represented at the Montreal Convention of the National Electric Light association. After the business meeting the members of the society and their friends visited El Dorado, Bolossy Kiralfy's summer resort at the Palisades on the New Jersey bank of the Hudson river. The visit was made at the invitation of the Palisades Amusement company and the Thomson-Houston company. The members of the Electrical society greatly enjoyed the spectacle of the "Destruction of Jerusalem," the concert and the fireworks, and an inspection of the magnificent electric lighting plant of the Thomson-Houston company. El Dorado is a very spacious amusement resort and is visited nightly by some 8,000 to 10,000 persons. The ground and the amphitheater are splendidly lighted by arc lamps.

The subject of cable communication with light ships is still being actively discussed. It is especially urged that the New South Shoal lightship, off the southern shore of Nantucket, should be connected by cable with that island. This light ship lies just to the northward of the track followed by all the great Transatlantic steamers bound to New York, and it marks the southern edge of the dangerous Nantucket Shoals. Were this lightship made a telegraph and weather signal station, not only could almost all incoming European steamers be reported in this city some eight or nine hours before reaching Sandy Hook, but vessels passing the South Shoal could be forewarned of dangerous gales passing northward along the gulf stream, or approaching from the west. Such weather warnings would be of very great utility to all shipping, big and little. By a curious coincidence an example of the valuable services that this particular light ship might render to shipping had it telegraphic communication with the mainland, was afforded this week by the breakdown of the Servia. When the vessel's crank-pin broke she was dangerously close to Nantucket Shoals and a few hours of strong southeasterly wind would have carried her into the breakers. She might easily have anchored within signaling distance of the light ship, however, and assistance could have been telegraphed for to New York and Boston, assuming the light ship to have cable communications with Nantucket. The *Herald* points out that the Five Fathom Bank Light vessel off Cape May, Cape Charles Light vessel and the new Outer Diamond Shoal Lighthouse off Cape Hatteras, are important stations which ought to have telegraphic communication to enable them to give storm warnings to vessels at sea. "Give these outlying stations the means of communicating electrically with the mainland, and they could easily signal to hundreds of vessels running into the teeth of a West Indian hurricane, a gale or a blizzard in time to enable shipmasters to avoid the danger."

Among the many suggestions for something startlingly big for the World's Fair, has been the proposal to erect an immense dome one thousand feet high. A correspondent of the New York *Tribune* improves on the idea by suggesting that the dome be built in the exact shape of the Northern hemisphere, with all the principal geographical characteristics of that hemisphere represented in relief on the outer surface of the dome. This includes continents, oceans, mountain ranges, islands, lakes, water sheds, river-basins, etc., all to be correctly represented in proportionate elevations and depressions. Besides this all the principal railway lines should be represented by paths or lights of steps so that visitors might take a trip in miniature through the different countries. The course of Transatlantic liners and coasting fleets and the routes of submarine cables would be illustrated on the oceans. The interior of the dome could be used to good purpose, es

pecially at night, for illustrating the constellations and planets of our solar system. Electric lights of various intensities would correspond to stars of different magnitudes. They should be so hung as to occupy a place in the dome to correspond to the actual position in space of the bodies they represent, so that from a given point (the one occupied by the earth) the lights would show our familiar groups of stars, but from other points new forms and groupings would appear, so that our well-known constellations would no longer be recognized as such, and our fancy would be free, as was that of the ancient astrologers, to imagine new outlines in the sky, and to name new constellations. This last part of the scheme seems to be scarcely practical, but the idea as a whole is an excellent one and if it could be carried out the geographical astronomical dome would be, as its originator says, a marvelous demonstration of the constructive powers and of the scientific status of our nation at the present time.

Death by electricity lurks in the ice cream freezer. A physician writes to the *Medical Record* giving the results of experiments with ice cream freezers in which he discovered galvanic action between the paddle and the containing vessel, the cream acting as the electrolyte. Salts of copper and zinc are formed and to those he ascribes the cases of ice cream poisoning which frequently occur. It is not readily apparent how copper salts can be formed by galvanic action in a zinc copper couple, since zinc is electro positive to copper, but if acid substances are used in the cream, copper salts could easily be produced without galvanic action. In any case a perfectly simple remedy for the danger suggested is to have all parts of the freezer of the same kind of metal, in which case there can be no galvanic action at all.

Judgment for $35,466 was yesterday entered against the Manhattan Electric Light company and the Harlem Electric Lighting company in favor of the Thomson-Houston Electric company on seven promissory notes of $5,000 each, made in October, 1890, by the Harlem company, and indorsed by the Manhattan company. Both these companies are closely connected in business. On June 12 last the Manhattan company obtained a judgment for $142 802 against the Harlem company. The latter company has a capital stock of $250,000 and that of the Manhattan is $2,000,000. The defendants claimed that the notes were accommodation notes and should have been paid into a certain syndicate; they have taken proceedings to set aside the judgment.

The trolley system has won a victory in Brooklyn after all. The State Board of Railway commissioners, after hearing further arguments reversed former decisions and gave Deacon Richardson permission to use the trolley system on about twelve miles of surface railways in Brooklyn.

W. L. H.

Minneapolis, Minn.

MINNEAPOLIS, July 11.—There is quite an interesting controversy going on between the Edison and the Thomson-Houston motors for precedence in the favor of the Minneapolis Street Railway company. The company has 110 Edison motors, 40 of them under 16 foot Jones cars, 60 under 18 foot Laclede cars, and 10 under Laclede open cars. Fires have rendered a number of these motors unserviceable and there are probably not to exceed 100 in actual use. The balance are Thomson-Houston motors, with which two or three of the principal local lines are equipped. Although no official announcement of the fact has been made, Thomson-Houston motors will be placed in all of the new cars. The inter-urban line equipment is now Thomson-Houston and is giving very excellent satisfaction. So far as that is concerned the general public is satisfied with either motor as the service on all lines, both inter-urban and local, is first class in every respect.

Local postoffice officials have received notification from Assistant Postmaster General G. F. Stone that the plan for inter-urban electric mail service has been deemed satisfactory by the department and that the inter-urban line has been declared a postal route, dating after the first of August. Mails will therefore be run every half hour between Minneapolis and St. Paul upon the electric railways after that date. Superintendent Perkins of the railway mail service, has announced that everything is in readiness to put this route in operation at that time. Twelve cars will carry mail boxes at first, and this number will be increased as necessity requires it.

The Brush Electric company will within a very few days award a very large contract for its underground work. The bids that have been submitted average about $100,000, but it is stated that the contract will be awarded for $93,000. The council committee on underground wires will have to take the matter under advisement and give its ratification before the contract can be closed, but it is expected that this committee will coincide with any suggestions that the Brush company may make.

The Stillwater, Minn., Electric Street Railway company is negotiating for a number of 50 horse power motors to take the place of the 30 horse power motors now in use on their line. The hilly nature of the city renders it necessary for them to have more power. It is also stated that they are about to use water power of the St. Croix river near Stillwater for generating electricity.

The car shop of the company in the interurban district is rapidly approaching completion and will afford facilities for all the cars used on the interurban lines. Pending its completion a long switch is used on University avenue, and some inconvenience is experienced in handling the cars necessary for the traffic on that line. The car shops in Minneapolis are now substantially completed, and the company is engaged in laying tracks from the east side lines to the building. The structure covers nearly the entire block and is one of the largest of its kind in the country. It is so situated that it is readily approachable from all the lines in the city, and a break-down need, therefore, cause very little, if any, delay. During the recent heavy thunderstorm in this city the power house of the company caught fire, and the building inspector claims that wires defectively insulated were responsible for it. Little damage was done.

The street railway company has determined to reject the renewal of the contract offered by the postoffice department for carrying letter carriers at the uniform rate $2 10 a month for each carrier. The government allowance is $900.00 annually, which is in addition to the $2.10 a month which each carrier has to pay. Hereafter the postmaster will purchase checks at 3 cents each, which will be given to carriers residing at the greatest distance from the postoffice, and if the carrier wishes to ride he must pay his fare as an ordinary citizen.

People in certain suburban d'stricts are waging unrelentless war on the electric companies, which still occasionally attempt to place poles or string wires on the streets. The manager of the telephone exchange and chief of the fire department joined in a consultation with the chief of police and building inspector the other day with reference to this work and the matter was finally compromised by giving the telephone company permission to string wires outside the conduit limits, and all opposition was withdrawn to the stringing of fire department wires. The street railway company has also had more or less difficulty in pushing its work on account of the objections constantly brought in to the city officials.

The Como avenue division of the University line will not be put in operation for some little time, as the viaduct over the Great Northern track on Fifteenth avenue, southeast, is not yet completed and there is no way of getting around it.

The street railway management has adopted a novel scheme for keeping the interurban line in good condition for travel. A number of street sprinklers have been arranged on motor cars and they will be run at regular intervals during the dry and dusty weather, on University avenue, between Minneapolis and St. Paul. These sprinklers are in readiness to be operated now and will be put on as soon as the condition of the avenue demands it.

F.

San Francisco, Cal.

SAN FRANCISCO, Cal., July 9.—For the past year or so the work of installing an incandescent electric lighting plant in the famous Palace hotel of this city has been progressing slowly, and now about 1,000 lights have been placed, and are burning nightly in the main offices, the great court and in the various parlors, dining hall, cafes, reception and billiard rooms. The Slattery alternating system is used, and the plant, when completed, will consist of at least 4,000 lights, making it the largest isolated incandescent installation on the Pacific coast, that of the Hotel del Coronado, Coronado, Cal., with 3,000 Mather lights being second. In the Palace hotel installation two 1,000 light Slattery alternating dynamos are placed in the basement of the hotel directly under the city cafe, and the noise proves quite disagreeable. To avoid this the dynamos are to be moved to the basement of a new seven-story office building that is soon to be erected on an adjoining block by the owners of the Palace hotel. The dynamos generate a potential of about 1,200 volts which is distributed throughout the basement and the courts of the building to the converters, the secondary current being at 50 volts, with a few circuits at 100 volts. The interior primary circuits are of Okonite wire, each being incased in interior conduit, then placed in individual moldings. All secondary circuits are of some solid rubber insulation, generally Okonite, and inclosed in conduits throughout their entire length.

John I. Sabin, general manager of the Pacific Telephone [illegible] will, when completed, be perhaps the finest in the city, and will be the pride of electricians generally. The new car- [illegible] the building.

A number of [illegible] meeting at [illegible] pany which will build and operate an electric railway from the Southern Pacific depot at Ione to Sutter Creek, a distance of [illegible] Jackson. The total length of the road will be about 25 miles. One hundred thousand dollars in stock was subscribed, ten per cent. of which was paid down, and already the surveys for the road are under way. This road will run through the section of country made famous during "the days of '49."

Theodore Meetz has made application to the trustees of Alameda, Cal., on behalf of the Oakland, Alameda and Piedmont Railway company, for an electric railway franchise along Santa Clara avenue to Versailles avenue, thence to Park street in Alameda, whence it will go northerly to the city limits. It is stipulated that work shall commence as soon as Santa Clara avenue is opened. No choice of system has yet been made.

Mr. Blaisdell of Alameda has also asked for a franchise for an electric road, which is to start from an intersection with the Meetz electric road at Park street and Twenty-third avenue, thence along Twenty-third avenue to the boundary line of Oakland, whence it is to be continued through Fruitvale and on to Highland Park. Work is to be commenced within six months after the granting of the franchise, and to be completed in one year.

Chas. F. Crocker, vice-president of the Southern Pacific company, which owns the horse cars and steam motor line running between Oakland and Berkeley, via Telegraph avenue and North Temescal, states that the Southern Pacific company has definitely decided to change the equipment to an electric road.

The Pelton Water Wheel company of San Francisco has shipped a plant of 400 horse power to an electric lighting and railway company in San Jose, Gautemala.

The tiny little brown wooden power house of the Spokane Cable Railway company at Spokane Falls, which stood picturesquely on the edge of the rapids of the Spokane river, has ceased to be an object of interest to those who cross the bridge below the falls to North Spokane. The equipment of the cable line has been changed to an electric road and now forms a branch of the electric system that has been constructed throughout the city by the Spokane Street Railway company. The present electric equipment consists of two 80 kilowatt Edison generators and sixteen cars, each having two 15 horse power motors of the Edison type.

The contract for the overhead and rail equipment of the Santa Cruz and Capitola electric railway has been awarded to the California Electrical Works. Dr. Thomas Addison of the Thomson-Houston company secured the contract for the car and station equipments.

Among the most recent visitors to the Pacific coast were: H. L. Lufkins of the C. & C. Motor company of New York; Chas. E. Brown of the Central Electric company, Chicago; C. M. Spaulding of the Electrical Supply company, Chicago; and C. F. Blackwell, president of the American Fire Alarm company of Boston.

Citizens of Santa Cruz, Cal., propose to place an electric street railway system in that city, while the people of Healdsburg, Cal., are endeavoring to organize an arc and incandescent lighting plant.

The Pacific Auxiliary Fire Alarm Telegraph company has shipped 200 auxiliary boxes to Seattle, which will be the second city on the coast to be equipped with that system. San Francisco has a great many auxiliary boxes, and the additional protection afforded by the system is recognized by the Pacific Insurance Union, which makes a reduction of from 5 to 10 cents in insurance rates.

A Los Angeles newspaper has made the prediction that the Electric Street Railway company of Los Angeles will eventually acquire most if not all of the horse and cable roads in that city. The purchase of the Second street depot line, reported about a month since, has been confirmed, and last week the Los Angeles & [illegible] road was absorbed, and will form a branch of the new system.

The Olympia, Wash., Light & Power company has offered to equip the existing horse car line in that city with electric cars for $10,400, and to operate the same, giving twelve minute service, for $120 per month. The line is two miles in length. It is proposed to install the Edison system, power being obtained from the Tumwater river.

The San Francisco Bridge company, which holds the

contract for grading and bridging about fifty miles of the Great Northern railway from Sand Point, Idaho, westward along the Pend d'Oreille river, has closed a contract with the Edison General Electric company for the Edison electric drill to be used in blasting. Throughout the entire distance the road will run along the river. The dynamos for operating the drills are to be placed on a barge, and current will be furnished from them to the shore, the barge being floated down the river as the work progresses. It is believed that this is the first time that electric drills have been used in railway construction.

An article appeared in one of the San Francisco newspapers recently announcing that the California Electric Light company contemplated the placing of an Edison station in San Francisco and that at least one million dollars would be put into the new enterprise. For two or three months it had been known that negotiations were in progress regarding station equipment of the California Electric Light company. For three or four years it had been remarked that its Jessie street station was altogether too valuable property for an arc lighting station, and that the site was an ideal location for an incandescent station.

The article referred to quoted Geo. H. Roe, secretary and general manager of the California Electric Light company, as saying that the details of the new scheme were not in shape for the public, but that they would be shortly. Mr. Roe has since stated that the Edison General Electric company has intended for a long time to establish a central station in San Francisco, and a number of its agents have been here at different times during the past two years. Nothing definite was accomplished, however, until quite recently, when Samuel Insull, vice-president and general manager of the Edison company was here to look over the ground, and, after concluding that a plant in San Francisco would prove a paying investment, offered to purchase the entire electric light and power plant, franchises, etc., of the California Electric Light company. This offer was considered by the Board of Directors of the local company and finally accepted. On July 1st last the Edison Light & Power company was incorporated with a capital stock of $3,000,000 and on the following day the entire plant, franchises and other property of the California Electric Light company used in central station lighting in San Francisco was transferred to the new corporation. The consideration for that transfer was $1,000,000 worth of stock of the Edison Light & Power company. Mr. Roe further stated that the new company would immediately commence the construction of its central station and expend $500,000 within the next six months.

In addition to the valuable franchises, etc, the plant turned over to the new company consists of about 3,000 horse power in Brush and Thomson-Houston arc lights, Brush constant current motor and Brush alternating incandescent circuits. The plant is divided between two stations, the old station being the Jessie street station referred to, which runs through from Jessie to Stevenson street in the block bounded by Market, Fourth, Mission and Third streets. The new station called Station "B," is down on Townsend street, between Third and Fourth streets and near the sea wall and railroad yards. Station "A," or the Jessie street station, is right in the heart of the city, being within half a block of the junction of Kearney and Market streets, the Palace Hotel and the *Chronicle* and Crocker buildings. It is admitted, therefore, that it is the intention to move the entire electric equipment to the Townsend street station and to convert Station "A" into the Edison station. To do this radical changes must be made and possibly a part of the building will have to be reconstructed. This arrangement will place all the high potential apparatus in the Townsend street station, where real estate is not held [illegible] can be [illegible] almost [illegible] station will be operated by the new company and all Edison circuits will be placed [illegible] that the new multi [illegible] triple expansion [illegible] for the Edison [illegible] the new station, [illegible] will be set up as the initial plant.

[illegible] light com- [illegible] present. [illegible] The [illegible] tem and patents for California, Oregon, Washington and [illegible] very valuable. The company still holds extensive interests [illegible]

company also proposes to enter actively into the electric railway business, and it is presumed that it will handle the Short system. S.

Milwaukee, Wis.

MILWAUKEE, July 13.—The city's street lighting contract with the Badger Illuminating company will expire on December 15th. The common council has adopted a resolution, which the mayor has signed, instructing the Board of Public Works to advertise for bids at once. The Badger Illuminating company tried to show that the resolution was illegal, and did its utmost to prevent the mayor from signing it. The Badger, with wires strung all over the city, has the inside track, but the Milwaukee Power & Lighting company, it is thought, will prove a more formidable competitor for the new contract than it did for the present one. They are the only companies operating arc lights in this city.

The Western Union Telegraph company is seeking to get permission from the common council to string all its wires in aerial cables running through the alleys, but Mayor Somers is determined that all electric wires, except those used for street railway purposes, shall be buried, and he will probably balk the Western Union. There is little doubt that he will veto a resolution extending the Western Union company's time for burying its wires until August 15th, by which time the aerial cable question will be decided. The Mayor seems to have the support of the people.

The interested parties have practically agreed upon an ordinance for the burial of electric light wires. It provides that all such wires shall be placed underground within five years from January 1, 1892; not less than 5 per cent. the first year, 10 per cent. the second year, 25 per cent. the third, 30 the fourth, and 30 the fifth year.

The common council has taken favorable action in the matter of extending the Milwaukee Power & Lighting company's franchise.

The injunction restraining the Milwaukee Street Railway company from building on the Mukwonago road to the Soldier's Home has been dissolved, the company having made a money settlement with the plank road people.

The work of transforming the Villard lines into an electric system is progressing slowly. The Illinois Steel company is slow in turning out the girder rails contracted for, and heavy flat rails are being used on Farwell avenue. C.

Pittsburg, Pa.

PITTSBURG, Pa., July 11.—About as quick a piece of electrical work as has been heard of in a great while in this part of the country was done by the Ohio Valley Electric Light & Power company of Sewickly, when the electric light plant was moved from the leased quarters on Centennial avenue to the company's power house at Quaker Valley. In order not to leave Sewickly streets and many houses in darkness it was necessary to move the plant and re-establish it between sunrise and sunset. Accordingly President E. P. Young, J. M. Uptegraff, the company's chief engineer, and several assistants took the work in hand at dawn. The machinery to be moved included two dynamos, which supply the current for forty arc lights on the streets and seven hundred and fifty incandescent lights in houses, and which weigh nearly two tons each, and a Westinghouse engine weighing nine thousand pounds. As soon as it was daylight, and while the engine was still so hot that the men in handling it were forced to use cotton waste, the work began, and by means of differential blocks the heavy machinery was hoisted on a heavy cart, which had been strengthened with big timbers, and was drawn by four horses. So diligently did the men work that by noon all the machinery had been hauled to the house at Quaker Valley, a mile away. There foundations had been prepared for the dynamos and the engine, but in addition to making them fast the pipes from the boiler to the engine had to be cut and fitted after the latter had been bolted down. But everything went right, and at seven o'clock, sooner than was really needful, the engine was in motion and the dynamos furnishing current as usual. Mr. Young and his colleagues are greatly pleased, as very few people in Sewickly are even to-day aware of the fact that the electric light plant has been moved at all. The electric plant is supplied with Westinghouse apparatus.

The Birmingham, Allentown & Knoxville Traction company was chartered yesterday at Harrisburg. The company is a [illegible] corporation, and the directors of the Birmingham Traction company are all interested in the new venture, which, according to the charter, has been organized for the purpose of establishing a factory for the manufacture of electric motors. It is supposed that the company will go into the manufacture of street railway motors, but under whose patent it will work and what style of motor it will turn out has not yet been developed. H. Sellers McKee, a millionaire of this city, is at the head of the enterprise.

The last Fourth of July was a great day for the electrical rapid transit companies of this city. The city has lately been presented a very beautiful park, of about three hundred acres, by Mrs. Mary Schenley, a Pittsburg lady and probably the richest woman in America. The Fourth of July had been decided upon by the city authorities as the occasion to give the first public demonstration of joy at the possession of such a beautiful piece of property, and in the evening about $5,000 worth of fireworks were let off for the amusement of the people. This of course made Schenley Park the Mecca for all Pittsburgers on the evening of that day, and as most of the electrical street car companies run their lines in the direction of the park they did a great business. It is estimated that the Pittsburg Traction company carried on that day about seventy thousand passengers; the Duquesne Traction company sixty thousand and the Second avenue Electric Street Railway company about thirty thousand. The low figure of the last named company is accounted for by the fact that its course does not go to the park direct. B. L. W.

Indianapolis, Ind.

INDIANAPOLIS, July 11.—The Board of Public Works has held two meetings to open bids for street lighting, but none was received, although numerous agents for the different companies have been in the city.

President Fowler of the Citizen's Street Railway company, closed a contract last week with the Thomson-Houston company for motors for new cars, and with a St. Louis car company for a large number of cars to equip the new lines. With the new machinery now being placed in the power house this company will be able to generate nearly 1000 horse power.

The Broad Ripple line is apparently abandoned. The contractors for laying the track, grading, etc., have brought suit against the Edison General Electric company for $12,000 damages for failure to comply with their contract and have levied on the wire, iron and other property in sight. M.

Detroit, Mich.

DETROIT, Mich., July 11 —At a session of the common council of this city last week the Detroit Street Railway company (which is merely a reorganization of the present City Railway company and the Grand River Street Railway company) and the Fort Street Railway company were granted franchises for a period of thirty years. In return the companies agreed to adopt some method of rapid transit, and also make some minor concessions in the matter of change of tickets, etc. It had been reported that the franchise was obtained through corruption of the aldermen, and this, together with the general dissatisfaction with the accommodations and service of the street railway companies, led to an indignation meeting, which was attended by all classes of citizens, and at which the action of the council was emphatically denounced. At the next meeting of the council last Tuesday the council room was filled with citizens, and the session terminated almost in a riot. The mayor sent in vetoes of all the ordinances extending the franchises, and his vetoes were sustained. There is no doubt that the street railway companies intend to introduce rapid transit, but they have not yet publicly announced their plans.

A new passenger transportation company has just been organized here with a number of three-wheel conveyances drawn by horses. They will carry eighteen passengers, and the intention is now to run regular trips on one or two of the main streets. The carriages arrived to day, and were paraded through the streets on exhibition.

Fire broke out in the engine rooms of the dynamo station of the Bay City Electric Light Works on the night of June 24th. The engines and dynamos were ruined; loss about $25,000. The city is left in darkness. It will take a week to put in new engines and dynamos.

Work is to be started on a new street railway in Grand Haven next week.

Justice Brown of the United States Supreme Court has decided a street car muddle in Grand Rapids by refusing to grant a permanent injunction restraining the Reeds Lake Electric road from coming down town into Grand Rapids by straddling the Valley City road for two hundred feet. The District Court held that the straddle was an infringement of the Valley City company's road rights, but Justice Brown held that the straddle was only a crossing, although a peculiar one, and therefore not to be stopped by the Valley City company. D.

Swedish telephones are furnished with an automatic contrivance for regulating the number of conversations.

PERSONAL.

Thos D Lockwood was in Chicago last week.

W. A. Clabb, president of the Law Telephone company, New York, left last week for an extended business and pleasure trip through France, Germany and other parts of Europe. He will not return before the 1st of November.

NEW INCORPORATIONS.

Equitable Electric company, Jersey City, N. J.; capital stock, $250,000; to manufacture and sell electrical devices of all descriptions.

Baehr Electric Manufacturing company, Newark, N. J.; capital stock, $50 000, buying, selling and manufacturing electrical apparatus.

Carolina Light & Power company, Aiken, S C., capital stock, $20,000; to furnish and supply Aiken with electric light and water, etc.

Herzog General Electric company, Newark, N. J.; capital stock, $1,000,000; to manufacture, sell and exploit all kinds of electrical appliances.

Eastern Electrical Supply company, Portland, Me.; capital stock, $250,000; to manufacture and deal in electrical appliances and supplies of all kinds.

Edison Light & Power company, San Francisco, Cal.; capital stock, $3,000,000; to generate, transmit and sell electricity, electric light, heat and power.

New England Electric Brush company, Portland, Me.; capital stock, $500,000; to manufacture and sell electric brushes under the patent of Alexander Stanton.

Inter State Electric Railway company, Milwaukee, Wis.; capital stock, $10,000,000; to construct and maintain an electric railroad between Chicago and Milwaukee

Enterprise Construction & Supply company, New Orleans, La ; capital stock, $50,000; to buy, sell and manufacture electrical and other machinery and supplies.

Kennebunk Electric Light company, Kennebunk, Me ; capital stock $100,000; supplying the towns of Kennebunk and Kennebunkport and Wells with light, heat and power.

Shelbyville Water & Light company, New York, N. Y. (incorporated in West Virginia); capital stock, $50,000; operating electric light plants, gas, water and power works at Shelbyville, Ill.

Birmingham, Knoxville & Allentown Traction company, Pittsburg, Pa.; capital stock, $1,000,000; construction and operation of motors and cables or other machinery for passenger railways, etc.

San Antonio Light & Power company, Pomona, Cal.; capital stock, $240,000; to manufacture, produce, generate and otherwise obtain electric light, power and heat from the waters of San Antonio Creek.

Amador Electric Railway & Light company, Sutter Creek, Amador county, Cal.; capital stock, $500,000; to construct, acquire, operate and maintain a line of railroad, and maintain and operate telegraph and telephone service along the line thereof.

Brighton Park Mutual Home & Investment company of Branchville, Prince Georges county, Md.; capital stock, $250,000; buying, selling, leasing, mortgaging, improving land; construction and equipment of a railway, and gas and electric lighting.

Vendomatic Apparatus company, Pittsburg, Pa.; capital stock $10,000; to manufacture and sell and operate automatic pneumatic or electric machines, or appliances for the display of cards, photographs, and other articles of trade. Incorporated in West Virginia.

ELECTRIC LIGHT.

An electric lighting plant is talked of in Arkansas City, Ark.

A St. Louis capitalist contemplates establishing an electric light plant in Batesville, Ark.

At Tallapoosa, Ga , the Vernon Light & Power company will, it is stated, double the capacity of its electric light plant.

The Badger Electric company of Racine has secured the contract for lighting the city with 150 arc lights for a period of three years.

Large gangs of men have been engaged for weeks in Louisville erecting poles and stringing wires for the electric lights with which it is intended to illuminate the streets of the city.

At a special election of the residents of Fairmont, Minn , it was decided to issue $15,000 worth of bonds for the purpose of instituting a system of waterworks and installing an electric light plant.

The Badger Electric company of Racine, Wis., has placed an order for an additional 18x42 Reynolds-Corliss engine. The company is at present engaged in remodeling its station, adding two condensers, another Thomson-Houston 1,300 light alternator and two 50 light Thomson-Houston arc dynamos.

A. N. Brady of Troy, N. Y., has purchased the property and plant of the Troy Electric Light company for $90,000. The sale is said to be a part of the plan begun by the Troy Gas company in the consolidation of the three gas companies some time ago to obtain control of the gas and electric light corporations in that city. Mr. Brady is a director of the Troy Gas company.

W. S. Coon, M A. Smalley of Wyandotte county, O., W. W. Taylor of Philadelphia and others have incorporated the [illegible] company at Newport, Ky., to erect electric light plants, construct waterworks, etc. The capital stock is $500,000.

According to statistics published by M. Wybauw, a Belgian authority, there are 544 arc and 9,507 incandescent lamps in use in Brussels; 240 arcs and 1,481 incandescents in Antwerp; 220 arcs and 4 931 incandescents in Ghent; 384 arcs and 2,040 incandescents in Liege; 665 arcs and 2,423 incandescents in Verviers; 1,500 incandescents in Charleroi, and 1,100 lamps of both kinds in Ninove.

ELECTRIC RAILWAYS.

The Rochester, N. Y., Railway company will extend its Sophia street line to the Driving Park.

The Raleigh, N. C., Street Railway company has let the contract for the erection of its electric power house, which is to cost $10,000.

The Houston, Tex , Street Railroad company has completed about twelve miles of electric lines, and will equip ten miles more within a year.

The contract for the construction of the West Asheville, N. C., and Sulphur Springs Electric railway, four and one-half miles long, has been let. It is stated that the Thomson-Houston company will furnish the electrical equipment.

The franchise for building an electric railroad from the Union railway station in Lynchburg, Va., to the Lynchburg & Durham station, which was granted a company represented by R. L. Miller, has been extended by the city council The company has, it is stated, awarded the contract to the Edison General Electric company for building the road.

Suit to restrain the Cicero & Proviso Electric Railway company of Chicago from crossing the tracks of the Minnesota and Northwestern Railroad company at grade in Harlem has been begun by the latter corporation. The complainant company avers that the crossing will interfere with its business, and that no condemnation proceedings have been instituted.

The South Harvey & Harvey Electric Dummy Railway company of Chicago has been incorporated with a capital stock of $50,000. The road will start at Homewood Station on the Illinois Central run east to Ashland avenue, thence north through South Harvey on Ashland avenue to One Hundred and Sixty-fourth street, and east to the steam railway station in Harvey. The road will begin operations with twelve passenger cars and two motor cars. The cars will run every half hour during the day, and every ten minutes in the morning and evening during the rush trips.

Articles of incorporation of the Lockport, N Y , and Olcott Beach Electric Railroad company have been filed with the secretary of state. Its term of corporate existence is to be 500 years and the length of the road is to be about twelve miles. The route is to be as follows: From the city of Lockport, thence through the town of Lockport, and the town of Newfane, to the shore of Lake Ontario, at the village of Olcott. The capital stock is placed at $120,000. The road will be part of the system intended to connect Rochester and Lockport by an electric railway along the Ridge road.

An electric road built by the Decauville company a short time since on trial at Bourg, France, has proved such a success that the municipality of the town has granted the director of the electric lighting department there a concession of thirty years for the working of the line. The cars, which were run for the first time last year on trial in the Champs Elysées, at Paris, are lighted as well as propelled by electricity stored in accumulators. The track is of only 23½ inches gauge, and curves of 16 yards radius are practicable. It is said that these cars have no difficulty in running up grades of 1 in 80.

One phase of the possibilities of the electric street railroad system was practically demonstrated recently by a young Rochester business man of a humorous turn of mind, says the Rochester, N. Y., *Herald*. One evening, in company with his sister, he boarded an east bound East Main street car near the Glen Haven terminus with the purpose of riding down town as soon as the course of the car should be reversed. When the end of the route was reached, the young man and his sister were the only passengers. The trolley rod was swung about, of course breaking the connection of the incandescent light within the car. In the instant of tunnel-like obscurity which ensued the humorous young man imprinted a sounding smack upon the back of his own hand. Then the lights flashed up again, just as the young lady exclaimed, "You horrid thing!" and bounced half-way along the length of the car. Her flushed face and generally discomposed manner, coupled with the foregoing circumstances, naturally disposed the motor man and the conductor to the belief that they had been the witnesses of an interesting love episode, and the series of grins and chuckles which they indulged in caused the young lady to alight hurriedly, that she might vent her wrath upon the sportive brother who had caused her discomfiture.

TELEGRAPH.

From Baltimore comes news that the transfer of the telegraph lines of the new Baltimore & Ohio Akron branch road to the Western Union, in accordance with the sixty-years' lease to the Western Union entered into by the Baltimore & Onio company in 1888, took place on July 6th. This agreement provides that the telegraph lines on every road or branch road acquired or constructed by the Balti-[illegible]

The sale is reported of the American Rapid Telegraph company [illegible]

The [illegible] to the control of [illegible] lines of the French Telegraph Cable company have been extended to [illegible] Martinique, [illegible] is expected that the line to Rio de Janeiro via Para will be completed by August 15th.

The second cable between France and Denmark, intended to duplicate that now existing between Oyne, near Calais, and the Island of Fance, in Denmark, will be laid during the latter part of this month between these points. This new cable will give more direct communication for French messages to St. Petersburg. It is the property of the Compagnie des Telegraphes du Nord.

During a recent storm Sergeant Farley, who had charge of the telegraph instruments at the Tremont police station, New York city, had an unpleasant experience. In the middle of the afternoon the man at police headquarters concluded to send out a general order. Sergeant Farley had got as far as "also you will strictly" in receiving the message when lightning struck the telegraph pole at One Hundred and Sixtieth street and Railroad avenue. The wire which was carrying the message to the sergeant was strung on that particular pole Fifteen poles were tumbled into the railroad cut by the combined effect of the lightning and the wind, and the sergeant was thrown across the office and brought up with considerable force against the railing. He was little the worse for the shock.

In last week's issue it was stated that the Western Union Telegraph company had won a victory at Milwaukee by a report of the judiciary committee of the common council in favor of an amended ordinance granting the company the right to run its wires overhead in a cable instead of burying them. It appears that the council at a meeting held since passed a resolution requiring the company to bury its wires by August 15th. It is now believed that Mayor Somers will veto this resolution. Together with his veto the mayor will probably recommend that the Board of Public Works suspend the work of chopping down the company's poles until action is taken on the ordinance now pending allowing the wires to be placed in aerial cables. The ordinance requiring that the company place its wires underground has been in force more than two years, but extensions have been granted from time to time until now Mayor Somers thinks it about time the company should comply with the law as the telephone company has done.

MISCELLANEOUS.

E. E. Ries, L. S. Greenfielder, O. M Dennis and others have incorporated the Ries Electric Specialty company in Baltimore, Md., for the manufacture, sale and installation of electrical apparatus. The capital stock is $25,000

The Southern Electric company has been incorporated at Lynchburg, Va., with C. P. Poole, president, and C.W. Poole, vice-president, for the purpose of manufacturing electrical apparatus. The capital stock is to be not less than $5,000 nor more than $25,000.

Lightning struck the big captive balloon in Chicago on July 6th The silken bag is said to have contained 150,000 cubic feet of gas, and the newspaper accounts state that flames 200 feet high rolled over an area of half a block. The balloon and its appurtenances were completely destroyed, and the loss is estimated at $30,000.

The United States Corporation Bureau of Chicago reports 313 new, completed corporations in the United States for the week ending June 26th, with a total capitalization of $80,937,150. Included in this number are thirty one mining and smelting companies with a capital of $22,175,000, and twenty-nine light, heat and power companies capitalized at $6,757,500.

The Empire Electrical company, now located at Brandywine, Pa., has bought a number of acres of ground in Cicero, near Chicago, and proposes to move. It is said to be the intention to form a practically new electrical supply company with a capital stock of $1,000,000. Several hundred men will, it is claimed, be employed, and work will be begun within sixty days.

On July 3d at St. Inigoes villa, St. Mary's County, Md., a peculiar and fatal accident occurred resulting from a lightning shock. St. Inigoes villa is a Catholic institution, and Father Boureaud thus tells the story: "On Friday night a tornado passed over St Inigoes [illegible] drenching rain. The scholastics, who were asleep on the top floor, were awakened by the rain pouring in on them and made hasty preparations to move their cots to dry places They were in all parts of the room when a blinding flash of lightning pervaded the apartment. After the shock seven of the young men were found lying on the floor. John B. Lamb of Boston, [illegible] New York, and James Watters of New York, [illegible] killed, and Daniel Quinn of New York, [illegible] Philadelphia, Mr. Raley of St. Mary's County, Md., and Mr. Neary were injured. A singular incident is that all the young men who were killed were in different parts of the room."

In the course of an [illegible] Machinery in Coal Mines" [illegible] application of electricity to [illegible] eventually to revolutionize [illegible]

ments in this direction have been practically and exhaustively carried on by experts, and the possibilities of electric adaptation have been accurately and scientifically placed. In mining machines it is already a conclusion that electric power is advantageous in economy of cost and increase of production. Motor power can be transferred from one point to another, as occasion requires, with but a minimum of trouble and expense, and the transfer of the product made with the same reduction in time and cost. The electric coal cutter now runs at the rate of 500 revolutions per minute, and on an average, inclusive of stoppages, can make a clean cut of 20 to 30 square yards of coal per hour. Fifty-five yards have been bored to an average depth of 3 feet 8 inches in seventy-five minutes, making a difference in the relative cost of cutting coal of 35 cents per ton in favor of the electrical apparatus. These advantages being established, the most important point in the use of electricity in coal mines has been the open question as to whether a motor would be likely to cause an explosion. This has been practically settled by inclosing the cummutator in a protecting air-tight casing. In special cases, where fire damp might leak into these covers, a constant supply of carbon dioxide is introduced from a steel cylinder, preventing the ingress of any explosive mixture. Switches are also inclosed and sparking prevented by a resistance coil of self-induction. It is practically demonstrated that in electric pumping, coal cutting and drilling macnines, the advantages of economy and efficiency are in favor of electricity, as compared with the older methods, and that it is but a question of time when electricity will be dominaut as a motor force in our coal mines."

TRADE NEWS.

The merits of the Thomson-Houston Motor company's system of electric tramways are attractively set forth in a finely illustrated pamphlet recently issued by that company. A number of highly successful installations of this character are described.

The Union Electric Manufacturing company of Bridgeport is manufacturing an incandescent lamp socket that has been received favorably by the trade. It is simple and durable, and there are few parts. Since its introduction there has been a lively demand for it, and it has evidently commended itself to popular favor.

The Pelton Water Wheel company has opened an office in New York at 235 Central building, Liberty and West streets. It is prepared to manufacture at this point water wheels and motors, together with water pipe, shafting, pulleys and other machinery connected with the development of power by the Pelton system.

Whipple's Reports for July states that the Chicago Electric Manufacturing company has dissolved This statement is untrue. J. D. Claghorn, the manager of the company, on being seen by a WESTERN ELECTRICIAN representative, was very indignant that such a report should be put in circulation, claiming that the concern was never in such good shape as at present.

Queen & Co., Philadelphia, are just now making a specialty of tachometers for indicating the speed of engines, dynamos and motors. These instruments are quite essential to the economical operation of a plant. By means of a tachometer it is possible to tell at a glance the exact rate of speed at which an engine or dynamo is running. For portable work a special iustrument is made which takes up but little space, and can easily be carried about. This tachometer is as accurate in its readings as the larger type mounted on a stroag base and designed for permanent attachment in the engine or dynamo room.

The increase in the sales of Perkins lamps by the Knapp Electrical Works during the last month has been greater than any preceding month of the year, The orders for these lamps have been coming in in large numbers from consumers who have had the lamps on trial for some time. Mr. Knapp reports that the lamp business has so increased during the last year that the Perkins company will be obliged to enlarge its manufacturing facilities again. Mr. Knapp also reports large sales of Safety wire, which he is now handling Mr. Knapp has a large stock of wire of all sizes at his headquarters on Franklin street.

[illegible] has recently taken some very large orders for electroliers and other electric light [illegible] in the Northwest. The company reports a large trade on these articles. The [illegible] increased for better [illegible] A recent [illegible] the [illegible] Central [illegible] and [illegible] the [illegible] new [illegible] the [illegible]

BUSINESS.

[illegible]

out a large line of cooking utensils, showing that aluminum is destined to go into very general use.

The West Side Car company of Boston is fast equipping the system with electricity, and as the work progresses the old cars are offered for sale. The company, it is said; operate more cars than any other line in the world, and when fully supplied with electric motors will have a plant that will command the admiration of the world.

Julius Andrea, Milwaukee, has discarded steam in his factory, and is installing a three horse power Eddy motor to run a part of the machinery. Later he will add a larger motor, taking the current direct from the Edison company's mains. Mr. Andrea is building up a very large business in Milwaukee, and by careful, painstaking work is deserving success.

The eighth edition of the revised catalogue of W. R. Ostrander & Co., 195 and 197 Fulton street, New York, has just been issued. It contains a complete list of their manufactures, comprising six systems, viz.: Speaking tubes, electric call-bells, electric burglar alarms, electric gas lighting, mechanical door bells, pneumatic call-bells, etc. The various appliances under each head are illustrated, and are arranged in a simple and systematic order.

The Pond Engineering company has recently received a large order for Armington & Sims engines from the Chicago Edison company for its central lighting station on Adams street. The engines are of 400 horse power each. The first engines in this plant were made by the Armington & Sims company, but since then tests of engines built by other firms were made. The Armington & Sims company was therefore greatly gratified on receiving the last order.

A new car, built by the Brownell Car company of St. Louis and known as the California Adjustable Car, patented by J. B. Blow, has just been put on the North Side cable line as a trailer. The car is a novelty, and in many ways would seem to have merit The seats are arranged to either face in or out along the side of the car. Windows are dropped down inside the back of the seats, so that when the seats are facing inward the windows can be put up, making a closed car for use in winter or in case of a storm. The car is handsome and solidly built, and has been put on the North Side line for exhibition purposes.

The Rockford Electric Works are placing the Mayo generator and their new "Iron Clad" motor on the market, and are meeting with well merited success. They have recently established a sales agency at Lincoln, Neb., and are desirous of placing agents in the field in other territory. Recently published testimonials from the *Chicago Tribune*, *Inter Ocean* and other Chicago establishments would indicate that the motors made by this company are giving satisfaction. A special feature will be made of isolated lighting, it being claimed that perfect regulation has been reached and that but little attention will be required after the plant has been installed. A large number of generators are under construction in the factory, and preparations are being made for an active fall season.

The Union Electric Works, 506 Springer building, are making the apparatus to be used by the American Electric Fence company, which is now being put on the market in Texas and Colorado. Preparations have already been made for the construction of a large amount of the fence. The parties owning the patent for California are advertising it in that territory as a protection against the rabbit pest, and it is likely to be put to general use so it is claimed for that purpose The Chicago company has devised a very fine converter, in the form of a large coil, and when power can be had, they are going to supply a small magneto generator to take the place of the battery and coil The Union Electric company has recently purchased several electrical inventions and is making a specialty of exploiting new devices.

ELECTRICAL PATENTS.

Issued July 7, 1891.

455,298. Electric Locomotive. Norman C. Bassett, Lynn, Mass.

In this locomotive the electric motor extends from axle to axle of the truck and is mounted thereon by spring bearings. Upon the armature shaft of the motor there are placed variable friction pinions which engage corresponding friction wheels fixed upon a countershaft, which shaft is geared to and swings about the axle as a center.

455,316. Annunciator. Manias Garl, Canton, Ohio

455,320. Telegraph Key. Robert W. Green, St. Thomas, Canada.

455,322. Trolley Pole Stand. James R. Griffiths, Allegheny, Pa.

455,339. Conductor for Electric Railways. Walter H. Knight, Cleveland, Ohio.

The last claim is:

"25. In an electric railway, the combination of an inclosing conduit, a supply conductor, a vitreous insulator having a spring-bearing, and a deadener therefor."

455,340. Electric Railway. Walter H. Knight, New York, N. Y.

In this system a contact device is carried by the car, the outer extremity of said device being pressed against the line conductor, while the inner extremity [illegible] on which the vehicle is mounted, to permit the accommodation of the device to the irregular paths followed by its ends respectively.

[illegible] the combination, with an electric motor and an [illegible] of a conductor, a supply [illegible] propelled thereby, and a contact device held against fore-and-aft movement by its connections with the vehicle and movable laterally about a horizontal axis."

455,341. Electric Railway. Walter H. Knight, New York, N. Y.

The yokes are provided with sockets with insulators seated therein and conductors attached thereto. The slot rails, extending through the pavement to form the upper part of the conduit, are suitably attached to said yokes.

455,342. Electric Railway. Walter H. Knight, New York, N. Y.

455,343. Electric Railway Plow. Walter H. Knight, New York, N. Y.

455,352. Electrical Watchman's Clock. Harvey S Park, Chicago, Ill.

455,366. Combined Fuse Block and Incandescent Lamp. Horace E. Swift, Boston, Mass.

455,398. Quadruplex Telegraphy. Charles D. Haskins, Brooklyn, N. Y.

In this system an extra helix is provided on the neutral relay magnets whose terminals are connected to the magnet terminals of an ordinary back contact relay.

455,410. Watchman's Time Detector. Abraham Newman, Brooklyn, N. Y.

455,420. Method of Electric Welding. Elihu Thomson, Swampscott, Mass.

In this method the metal is cooled just back of the weld and between the same and the places where the current bearing electrodes form contacts.

455,421. Securing Metal Bands on Wooden or Other Articles. Elihu Thomson, Swampscott, Mass.

455,440. Watchman's Time Recorder. John A. Lannert, Cleveland, Ohio.

455,446. Grave Annunciator. William H. White, Topeka, Kan.

455,447. Conduit for Electric Railways. William Bradley, Fort Wayne, Ind.

455,451. Diaphragm for Electrolytic Cells. Ernest A. Le Sueur, Ottawa, Canada.

455,454. Electric Railway. Edwin W. Rice, Jr., Lynn, Mass.

In this system two supply conductors attached to separate generators, and parallel with the road, are each at separate times made to propel the car by means of a suitable arrangement which brings the propelling motor in circuit with either of them at one time.

455,488. Friction Gearing for Dynamos. Frederick L. McGahan, Indianapolis, Ind.

455,510. Train Signaling Apparatus. Linwood F. Jordan, Somerville, Mass.

455,517. Multipolar Dynamo. Andrew L. Riker, New York, N. Y.

455,518. Carbon Brush and Holder Therefor. Andrew L. Riker, New York, N. Y.

455,520. Pulsating Current Reciprocating Electric Engine System. Charles J. Van Depoele, Lynn, Mass.

455,524. Electric Meter. James J. Wood, Brooklyn, N. Y.

455,532. Self-winding Electric Clock Fred L. Gregory, Niagara Falls.

455,545. Electrical Walking Toy. John B. Kibler, Minneapolis, Minn.

455,559. Lamp Socket and Switch and Circuit Closer Therefor. Henry P. Ball, Brooklyn, N. Y.

455,575. Electric Meter. Johan W. T. Olan, New York, N. Y.

455,576. Electric Arc Lamp. Johan W. T. Olan, New York, N. Y.

Claim one reads:

"The combination, with the carbons or electrodes of an arc lamp and inclosing globe therefor, of a tube extending from the base thereof and containing a column of liquid, said column supporting one of the lamp carbons, and means for separating the carbons to form an arc"

455,581. Electric Motor Car Truck. John F. Seiberling, Akron, O.

455,631. Apparatus for the Defecation of Saccharine Juices by Electricity in the Manufacture of Sugar. Elias Maigrot and Jose Sabates, Havana, Cuba

455,680. Electric Belt. Charles A. Bogardus, Syracuse, N. Y.

455,683. Transmission of Alternating Currents of Different Phase. Michael Von Dolivo Dobrowolsky, Berlin, Germany.

455,693. Galvanic Battery. Henry C. Sample, Ravenswood, assignor to Hugh W. Matthews, Chicago, Ill.

455,696. Switch board for Electric Fence Stations. David H. Wilson, Normal, Ill.

455,711. Electric Motor. Lemuel G. Goode, Jersey City, N. J.

455,722. Support for Telephones. William J. Myers, Allegheny, Pa.

455,726. Electric Motor or Generator. Walter F. Brown, St. Paul, Minn.

The last claim reads:

"5. The combination, with the commutator of a reversible dynamo or motor, of brush supports on opposite sides thereof, arms secured at right angles with and adjustable along said supports, standards adapted to be secured upon either side of said arms and adjustable along the same, and brush holders and brushes carried by said standards."

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and is **guaranteed to be waterproof, and will not deteriorate, oxidize or crack,** and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

A Choice List of Summer Resorts.

In the Lake regions of Wisconsin, Northern Michigan, Minnesota, Iowa and the two Dakotas there are hundreds of charming localities pre-eminently fitted for summer homes. Among the following selected list are names familiar to many of our readers as the perfection of Northern summer resorts. Nearly all of the Wisconsin points of interest are within a short distance from Chicago or Milwaukee, and none of them are so far away from the "busy marts of civilization" that they cannot be reached in a few hours of travel, by the frequent trains, over the finest roads in the Northwest—the Chicago, Milwaukee & St. Paul Railway and Milwaukee & Northern Railroad:

Oconomowoc, Wis.	Clear Lake, Iowa.
Minoqua, Wis.	Lakes Okobeji, Iowa.
Wankesha, Wis	Spirit Lake, Iowa.
Palmyra, Wis.	Fronte-nac, Minn.
Tomahawk Lakes, Wis.	Lake Minnetonka, Minn.
Lakeside, Wis.	Ortonville, Minn.
Kilbourn City, Wis.	Prior Lake, Minn.
(Dells of the Wisconsin.)	White Bear Lake, Minn.
Beaver Dam, Wis.	Lake Madison,
Madison, Wis.	So. Dakota.
Delavan, Wis.	Big Stone Lake,
Sparta, Wis.	So. Dakota.
Pewaukee, Wis.	Elkhart Lake, Wis.
Wausaukee, Wis.	Ontonagon, Mich.
Marquette, Mich.	Mackinaw, Mich.

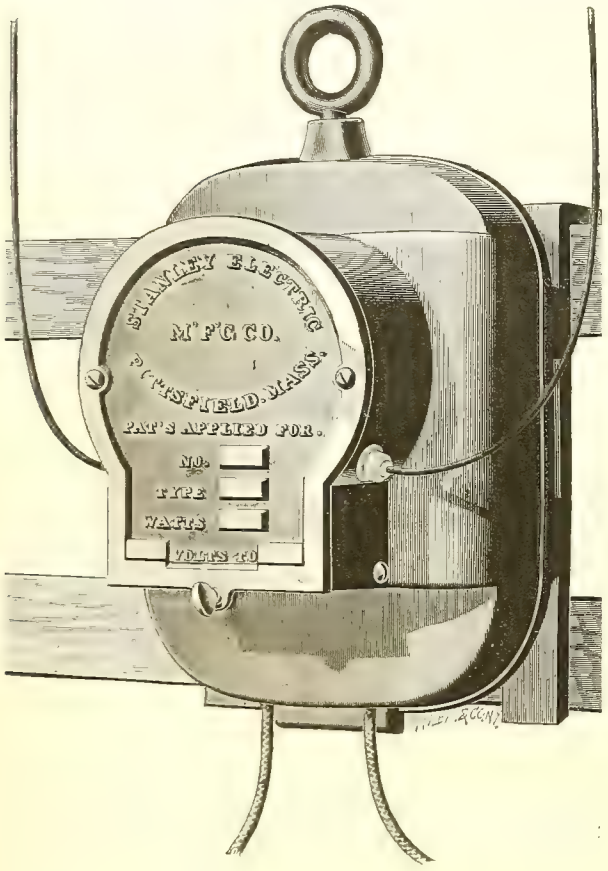
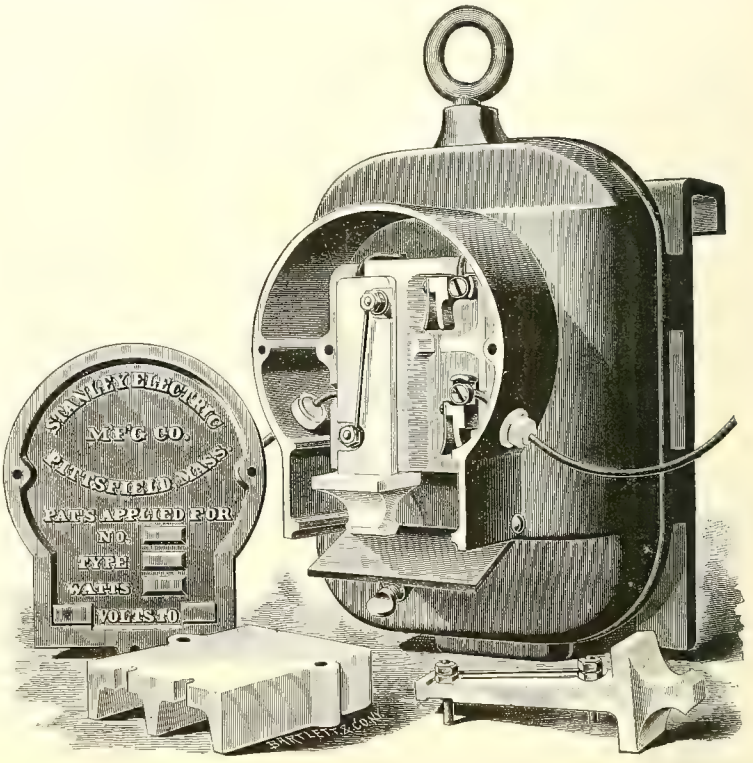
102 and 104 MICHIGAN AVENUE.





We say that the "Stanley" is the most efficient Transformer made, but the best way for you to back our judgement is to try one. This we will be glad to have you do, and if they are not as we claim, it costs you nothing. We stand behind the returns.

Try a No. 8 capacity 40 16 c.p. lamps.

We have had several struck by lightning but none damaged the fuse did the rest.

DOUBLE CARBON LAMPS

Afford the Only Reliable and Efficient Means for

ALL NIGHT ELECTRIC LIGHTING.

All other devices are crude, expensive, and unsatisfactory.

THE BRUSH ELECTRIC COMPANY

Has established its broad foundation patent for Double Carbon Arc Lamps, No. 219,208, having ***won four distinct infringement suits*** in the United States Courts, two of them on final hearing, the decisions being rendered by Judges Gresham, Blodgett, Brown and Ricks.

The public is warned against the use of infringing lamps or any crude substitute for the Brush invention.

ARC LIGHTING APPARATUS,
ELECTRIC MOTORS AND GENERATORS,
ALTERNATING CURRENT APPARATUS.
INCANDESCENT LIGHTING MACHINES,
CARBONS FOR ARC LIGHTING,
ETC, ETC, ETC.

THE BRUSH ELECTRIC CO.,

CLEVELAND, OHIO.

FORT WAYNE ELECTRIC CO.,

FORT WAYNE, IND.,

—MANUFACTURERS OF THE—

SLATTERY INDUCTION AND WOOD ARC SYSTEM

—OF—

ELECTRIC LIGHTING.

THE MOST PERFECT OF ANY.

For references as to the merits of these systems, inquire of the local companies, the operators, or the customers in the large cities of this country where these systems are now being used almost exclusively after other systems have been tried and thrown out—Philadelphia, New Orleans, Cincinnati, St. Louis, Kansas City, Louisville, Detroit, etc.

WE MAKE ALL STANDARD SIZES OF

INCANDESCENT LAMPS FOR THE ALTERNATING SYSTEM.

Also Arc Lamps of Standard Sizes, 2,000 c. p., 1,200 c. p. and 800 c. p.

Main Office and Factory, FORT WAYNE, IND.

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, unequaled for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Vol. IX. CHICAGO, JULY 25, 1891. No. 4

Electricity in a Chicago Rolling Mill.

In these days of heavy currents and high voltages one's attention is drawn oftener to matters pertaining to electric power and lighting equipments than to the multitudinous small devices through which electricity becomes a most useful agent in the workshop or factory. The assertion may be ventured that a tour of the many manufactories in and about Chicago would reveal a number of ingenious applications of electrical apparatus, worked up by the amateur, perhaps, but doing good work nevertheless, and on this account deserving of more than a passing notice.

The tendency among manufacturers is to employ about their plants men of technical education, and these, coming oftentimes directly from schools at which the electrical engineering course receives the closest attention, are not long in finding a way of introducing improved and thoroughly scientific methods.

As an instance of what is being accomplished by a few of those who call themselves "amateurs," there may be mentioned two simple yet very useful applications of electricity now in service in the rail mill of the south works of the Illinois Steel company at South Chicago. The devices referred to are an electrical recording rail counter and an ingenious printing telegraph. The working of the two sets of apparatus will be understood by a reference to the illustrations.

From Figs. 1, 2, 3 and 4 there may be obtained a very clear idea of the construction and operation of the electric rail counter. By means of this mechanism and a few cells of battery a tally of the number of rails rolled is kept in the office of the superintendent.

Fig. 1 shows the location in the mill of the water-tight and heat-proof contact maker, or key, through which an electrical impulse is sent into the office to operate the register or counter proper. This last mentioned device, Fig. 2, consists merely of an electromagnet arranged, as shown, to operate a lever escapement connected with a train of gears so proportioned and numbered as to constitute a counter. The contact maker, shown in position in Fig. 1, is simplicity itself, and after a glimpse at the cuts, Figs. 3 and 4, showing the details, the reader will doubtless imagine that the construction was a comparatively easy task. For the benefit of the uninitiated, though, it must be stated that the position of the apparatus at the rail is such that it is subjected to about as hard usage as one could well imagine. Splashed with water and in the closest proximity to the red-hot rails, and thus alternately cooled and heated, it is not to be wondered that the present design of the waterproof casing inclosing the one moving part was arrived at only after much experience and several disappointments. As will be seen from Figs. 3 and 4, the contact lever proper is mounted on a short, stout spindle within a casing of 4-inch pipe. This upright spindle is keyed into and forms a part of another lever below and on the outside, which projects in front of the rail. The lever at the rail is kept in position by a spring as indicated. As the rails come along from the saws one after another, this lever is pushed outward and thus makes one contact for every rail. The simple arrangement by which a good rubbing contact is secured is so clearly illustrated that no further explanation is required.

The printing telegraph system illustrated by Figs. 5, 6, 7, 8 and 9, is, as a matter of course, more complicated than the counter. Its object is to print on a tape, at the finishing end of the mill, where the stamping machine is located, the heat numbers of the ingots, the ingot numbers, and the number of rails in each ingot, so that the proper heat and ingot numbers may be stamped upon every rail that leaves the mill. In addition to these numbers, the "pit" and "hole" numbers, i. e., the furnace numbers, are also dispatched.

The system in its entirety consists of a receiver, Fig 5, a transmitter, Fig. 6, three connecting wires and eight cells of gravity battery.

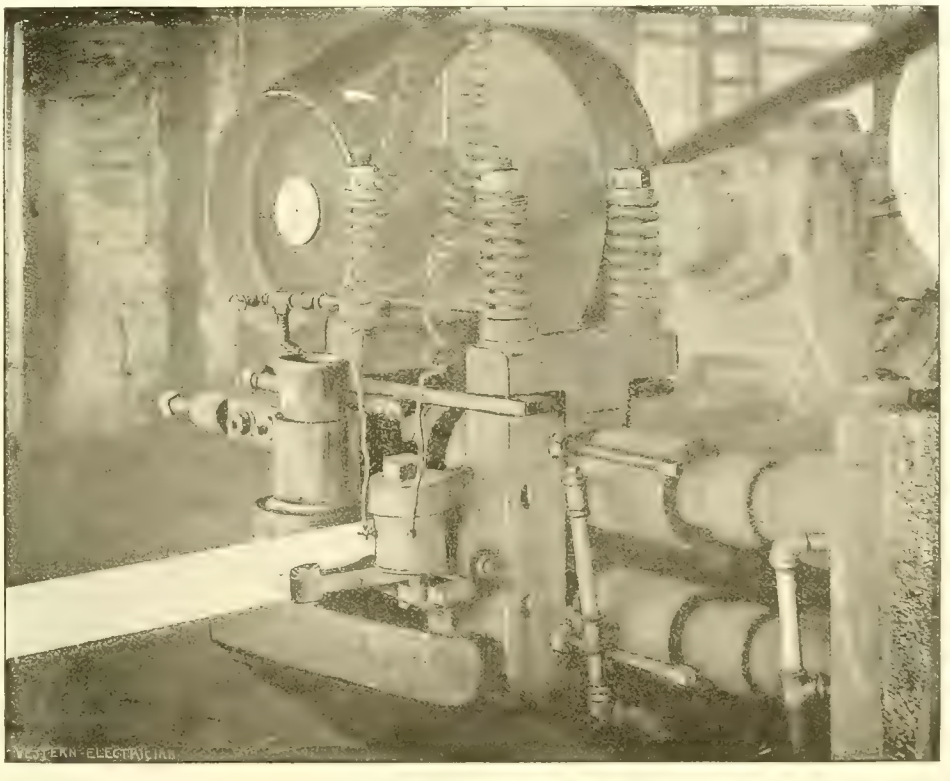

FIG. 1. ELECTRICITY IN A CHICAGO ROLLING MILL.

The receiver on which the tape is printed is located at the finishing end of the mill not a great distance from the point at which the contact lever of the rail counter is placed. This machine is in charge of a boy who records on a blackboard for the use of the stamper the numbers and letters as they are printed on the tape. The transmitter is operated by a man at the "pits," or reheating furnaces, at the further end of the mill, about 350 feet from the stamping machine.

To understand the details of this printing telegraph system it will be necessary to refer to the lettered parts in the diagrams and also to remember that two circuits are employed. It will be understood from Fig. 1 that while there are two circuits only three wires are needed, common return wire being used. From Fig. 7, in which is shown the transmitter with the dial face removed and also three sectional views, it will be seen that the transmitter consists essentially of a commutator ring *C* and a contact ring *B*, between which there may be revolved a contact lever *L*. The contact lever is shown more clearly to the left in the cut. This last named part can be turned around in only one direction, any back motion being prevented by a rachet wheel *K*. The part *D* of the contact maker bears against the inner face of the commutator ring *C* and as this arm *A* is directly connected with the battery (see diagram of circuits, Fig. 9), a revolution of the crank over the segments sends impulse after impulse of current to the receiver at the other end of the mill. These impulses act on magnet *M*, Fig. 8, and serve, by means of the lever escapement *E*, to produce a synchronous movement of the type wheel *T*.

To make the impressions upon the tape after the type wheel has been set by the impulses due to the movement of the little contact block *D* over the segmental face of *C*, the push button *P* in the transmitter, Fig. 7, is brought into play. When the crank has been moved around to a number or a set of letters on the dial, the button *P* is pushed in so as to make contact with ring *B*. As block *D* is at this moment in such a position that it is insulated by one of the segments of ebonite which are dovetailed into ring *C*, the contact between the crank and the other ring *B* serves to send current into magnet *N* of the receiver. Magnet *N*, lifting lever *L*, presses the tape up against the type and thus prints the symbol corresponding to the one on the dial to which the crank had been turned.

The upward movement of lever *L* serves also, by means of the escapement *F*, to move along the type into a position to receive another impression. The brass feed rollers *H* are actuated by the clock spring *S*. This spring is wound every 24 hours and feeds out from 200 to 250 feet of tape. *I* is the ink roller. The tape is wound up on the spool *W* by the slipping belt *V*. It may be mentioned, too, that there is a "dog" to prevent backward motion, which would throw the type wheel out of synchronism relative to the crank *A*.

The rail counter was devised by H. S. [illegible] of the south works of the Illinois Steel company, and the printing telegraph was made after designs prepared by C. A. Trube, also of the south works. For the photographs of the apparatus the WESTERN ELECTRICIAN is indebted to W. Clarke Cain, assistant superintendent of the rail mill.

An Electric Road for Chicago's West Side Suburbs.

It is reported that the Harrison Street and Des Plaines River Electric railroad company, which was recently incorporated at Springfield, will begin actual construction as soon as possible.

It is the intention of the company to start the road as near Western avenue, Chicago, as possible and run it west on a line near and parallel with Harrison street to the Des Plaines River, a distance of six or seven miles. The road will be just south of Harrison street, and will pass near Waltheim and Cicero [illegible]. It is the ultimate intention to obtain a right of way into the city if possible. The nearest competitor to the north of the proposed road is the Wisconsin Central main line, which has no suburban trade, while to the south there is an open field, with many new subdivisions springing up, and hundreds of houses building. That part of the West Side through which it is proposed to run the road is without adequate transportation facilities.

The Telephone in '93.

By Herbert Laws Webb.

A good many journals, both electrical and political, have a fondness for airing their opinions on the present status of the telephone industry, and its prospective status two years hence, when the Bell patent shall have expired. According to some of these journals the public is charged an excessive price for telephone service at present, and in '93, when the "grinding monopoly" is at end, the same useful commodity will cost next to nothing at all. If we are to believe these journals, in two years' time telephones will be

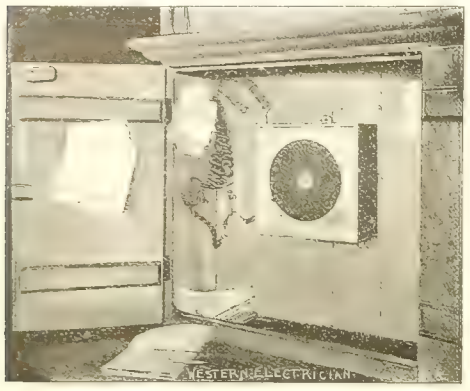

FIG. 1. ELECTRICITY IN A CHICAGO ROLLING MILL.

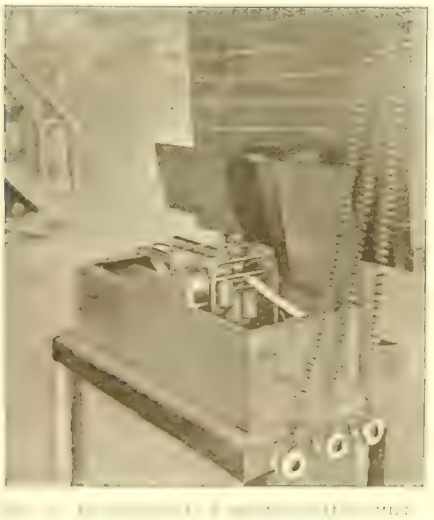
so cheap that, as we read is the case in Honolulu, every street soda water vendor will be connected with the exchange, and thirsty patrons will order their drinks from free "pay-stations" a block or two off.

To those who indulge in these fanciful theories it has become an article of faith that the entire telephone business is bound to stand and fall by the receiver patent. Given the expiration of that patent the field is free from competition, and the existing telephone companies must either lower their rates to starvation point or go to the wall. Some years ago, when the industry was young, weak and undeveloped, that might have been the case, but to day matters are on a very different footing. If the Bell patent had been broken down by any of the strenuous attacks made on it, then indeed some such situation might have come about as is prophesied by many for '93. In that case the numerous devices that go to make up a complete telephone system would have been distributed among many different companies instead of falling into the hands of one, and competing systems could have gone ahead and fought with each other and cut prices, or amalgamated and made "combines" in the same way that they have in the electric lighting industry.

Referring to the old telephone patent suits reminds me that the public, duly enlightened by the political press, entertained remarkable notions as to the possible result of the litigation, to an even more curious extent than those which



acquired practically all that there was in the telephone business, because at that time the industry was completely in its infancy, and there was very little but the telephone itself and some very crude and inefficient switching apparatus. In 1893 there will be given to the public the Bell telephone receiver, and the right to transmit speech by means of undulatory currents of electricity. In the words of a famous poet, "only that and nothing more."

Now the question arises, what will the public do with the receiver and the undulatory currents when it gets them? According to the newspapers it won't be happy until it does get them, but when the long wished for acquisition takes place the discovery will come that it is not worth nearly so much as it seemed to be from afar off. In this case truly distance lends enchantment to the view.

The motto of most newspapers should certainly be "writ large" at the top of the editorial page. "Where ignorance is bliss, 'tis folly to be wise." The newspapers, when they discourse about the telephone, believe, or pretend to believe, that the receiver patent having expired, the telephone business will be open to all comers, and that telephone service will be furnished for half or less than half the rates that are charged at present. If they would look a little farther into the question, they would find that the telephone receiver is one of the smallest items in the complicated collection of apparatus and machinery, large and small, which go to make up a telephone system. Do the newspapers or does the public imagine that all these countless devices, instruments, circuits and systems will be thrown in gratis with the receiver in 1893? To believe so would be to reveal a state of mind simple and confiding to the last degree; yet this belief is implied in the supposition that we are to have free telephony in '93.

When the American Bell Telephone company bit upon the ingenious and highly successful policy of leasing in-

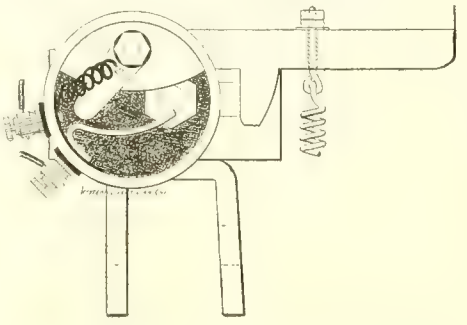


FIG. 3. ELECTRICITY IN A CHICAGO ROLLING MILL.

stead of selling the instruments for which it holds patents, that policy found a natural sequence in the acquisition of the patents for every other form of instrument and apparatus connected with telephony. Transmitters, switch-boards, bells, spring jacks, repeating coils, annunciator drops, ringing-keys, listening-keys, testing circuits and myriads of other devices and circuits are patented, and the patents are held by the Bell and its licensees. In any case the inventions would have been made and patents would have been taken out, and the patentee would have been paid for his ingenuity and trouble, so that to the public it makes but little difference whether the patents are owned by the American Bell Telephone company or by individuals, but to the mythical companies who are going to inaugurate competing systems in '93 it will make a very considerable difference.

Of course these patents form as it were a very strong inner wall of defense, which will prove a formidable obstacle to those intending to compete with the existing telephone companies, but there are outer works of a nature and strength which it will be very difficult to overcome. The chief of these is the strongly established position in which all the telephone companies in the large cities of the country are entrenched. Every day it is becoming more difficult to run wires from point to point. Overhead they are prohibited by the municipalities; underground the municipality steps in again, and says the streets shall be disturbed no more. There is a limit to the number of house holders, who for love or money (it is very seldom except for the latter) will permit fixtures to be placed on their roofs, or wires to be strung over them. There are a few other difficulties which he who runs wires in cities has to contend with, but these are the principal ones, and when attempts are made to add a few thousand wires to those already existing in all our large cities their importance will be duly appreciated.

Another difficulty in the way of active competition will be the dearth of real telephone engineering talent. To [illegible] equipped with all modern [illegible] switching apparatus, and [illegible] with all the complications, they intro-

duce—requires a very high order of electrical engineering ability, only acquired as the result of years of experience gained step by step with the growth of the industry itself. Even as the industry stands to-day there are comparatively few men who have this ability or this experience, and a modern telephone exchange cannot be designed, equipped and maintained by men new to the art. Such men would have all the old problems to conquer and solve over again in addition to the new ones which come up almost daily, and on the solution of which a concentration of effort, investigation and experiment is directed in a manner unparalleled in the electrical industries, excepting, perhaps, at

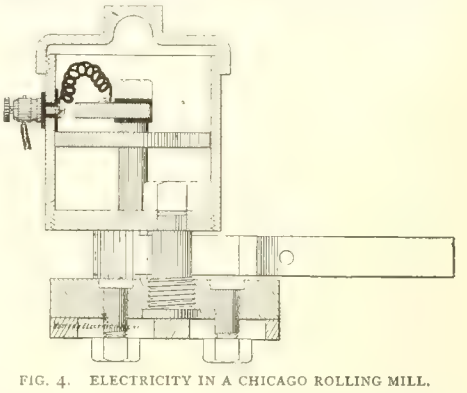

FIG. 4. ELECTRICITY IN A CHICAGO ROLLING MILL.

Llewellyn Park. At present the telephone companies all over the country profit by the knowledge thus systematically acquired, and their subscribers benefit by the results thereof, but the new comers would enjoy no such advantages. Many mistakes would be made, and in telephone work mistakes cost money in a dozen different ways. Here again the outlook for competition is rather a poor one.

The equipment of a large telephone exchange involves the expenditure of a considerable amount of capital, but its maintenance, including that of subscribers' instruments and lines, is a work that is not only expensive, but requires the most careful organization and supervision, both from a technical and executive point of view. A large staff must be employed for this work, and its members must receive systematic training and instruction from their superior officers in order that the work may be efficiently carried out. Records must be kept in order to trace the responsibility for any failure at any of a dozen different points in a subscriber's line, and in these records the daily history of the entire plant has to be entered from slips and memoranda. The intricacies of such work as this—which is absolutely necessary in order to maintain at its utmost efficiency a piece of machinery whose complexity is paralleled nowhere outside the human body—are not learned in a day, nor carried out smoothly, except by a large and well organized

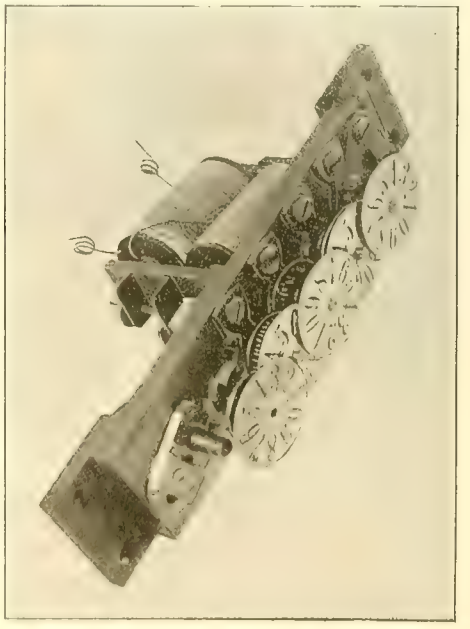

FIG. 2. ELECTRICITY IN A CHICAGO ROLLING MILL.

staff. In short, a modern telephone exchange is a very expensive concern to run.

It is questionable whether there will be any general reduction of telephone rates when the Bell patent expires. Large telephone plants become more expensive to equip and maintain every day, and the saving to the companies by the abolition of royalties on the receivers will be more than offset by the heavy fixed charges entailed by the

maintenance of extensive systems of underground cables. Cheaper classes of service may be introduced to meet any demand for lower rates. But to assume that in '93 good telephone service will be a very much cheaper commodity than it is at present is to argue without knowledge of the subject. Of late years the expense of installing large telephone exchanges has increased, owing to the very general introduction of underground work. Underground cables are far more costly than overhead wires, as regards equipment, and experience has yet to show that they are not more costly to maintain. They are certainly far less efficient as regards the service, and they introduce many new engineering problems in the equipment of the exchanges themselves. It would be no small undertaking to found a corporation to carry on telephone service in a large city; it would be an undertaking requiring a very large capital, and it is doubtful whether the capital would be forthcoming in view of the slender chances of securing an adequate return for it.

No unprejudiced observer who is at all acquainted with the inner workings of a telephone system can deny that the chances are slender indeed. There will probably be competition in the private line business and in small systems for large buildings or for connecting up a few houses close together; in fact, where small exchanges can be established competition will no doubt spring up. No individual and no collection of individuals is likely to start rival telephone exchanges in large cities either for the fun of the thing or for glory. Unless it were believed that there existed a good chance of making money in such a way capital is not likely to be attracted to the undertaking. The odds against there being any prospect of making money in opposition to the very completely laid out systems now existing in all the large cities of the country are so overwhelming that it is very improbable that any such competition will spring up.

One more obstacle may be mentioned, and that is the long distance service. The Long Distance Telephone company has interlaced the eastern states with a network of superbly built lines, which represent a vast outlay of capital. A system which should efficiently compete with these lines would be practically out of the question for several reasons, the difficulty of obtaining way-leaves for one; in any case it could only be built up in the course of several years and by the employment of capital running well into seven figures. The Long Distance company gives a splendid service and provides a means of rapid communication which has become absolutely indispensable to a large percentage of the subscribers to the local exchanges in most of the large towns. How long would it take for new companies to duplicate these conditions, and how much cheaper could they do the work than it is done at present?

It would seem, after all, if the present situation is soberly and intelligently considered, that the telephone situation in '93 will not materially differ from that which exists to-day. The obstacles in the way of extensive competition are numerous and formidable enough to convince any one who takes the trouble to examine them closely that extensive competition is practically impossible. The companies will go on steadily introducing improvements, which they are constantly doing—the political press, which affects to believe that all improvements are suppressed, to the contrary—and extending their systems. Telephone subscribers will learn in time that telephone service costs a good deal to furnish, and if in '93 they find that they are getting more secure and reliable communication, with improved facilities in every direction, there will be few inclined to grumble or cry out for the cataclysm in telephone affairs that in some quarters seems to be expected and hoped for.

Proposed Harvey Electric Road.

Articles of incorporation were recently issued to the Harvey Transit company of Chicago to construct a railroad in Harvey, Ill. presumably to be operated by electric power. Mr. Stanwood, one of the incorporators, informed a representative of the WESTERN ELECTRICIAN that the road would be constructed in sections of two and one-half miles. Work has not yet been begun on the road, nor has the exact route been decided upon. It is the intention to construct about seven and a half miles of road.

Electricity at the World's Fair.

It now appears altogether likely that there will be a temporary electric plant on the World's Fair grounds to supply light and power during the work of construction. At first, as has been heretofore noted in this paper, it was thought that it would be more economical to secure current from some one of the South Side central stations, and several companies were invited to put in bids with that end in view. Now, however, as the magnitude of the work in hand becomes more apparent, it has been thought best by the authorities of the electrical and construction departments to put in a temporary plant as soon as possible. This conclusion was hastened by the decision to employ electricity to furnish power for building operations. Several of the contractors have expressed their willingness to employ electric power if they can obtain it as cheaply as steam, and it is thought that this condition can be complied with. At first the power will be chiefly employed in operating saw-mills to manipulate the large quantities of lumber required for the huge wooden buildings that are now, or will shortly be, in process of construction. Another consideration that has led to this decision is the distance separating Jackson Park from the nearest central station. Probably two or three miles of heavy copper wire would be required, if the work were done by contract, which would, of course, greatly increase the expense.

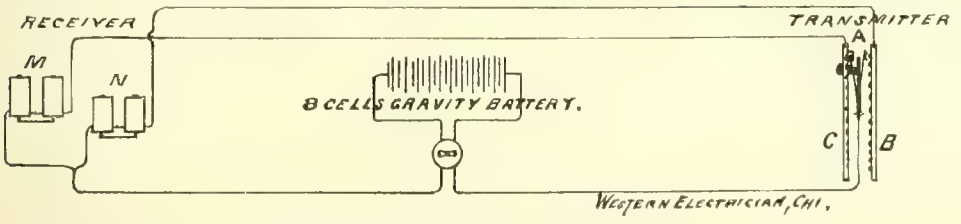

FIG. 9. ELECTRICITY IN A CHICAGO ROLLING MILL

The location of the temporary power house has not yet been definitely determined, nor have the specifications been completed. Arrangements will probably be made for an installation capable of supplying 250 arc lights, 1,000 incandescents and at least 300 or 400 horse power for motor service. But of course only a portion of this will be used at first.

In pursuance of his plan of personally conferring with all the leading electricians of the country, Chief Barrett paid a flying trip to Fort Wayne and Indianapolis, Ind., last week. He was accorded a cordial reception, and came back well satisfied with the results of his journey. He reports that everybody he met appeared to take the greatest interest in the electrical features of the exposition, and reporters importuned him for interviews at every turn. This department, whose happy faculty of gaining the friendship of [illegible] it is not the intention to use steam power in any building but the Mechanical Hall. The applications for space are phenomenal. We have now 140, and these embrace everything in electrical science, from a singing doll to a locomotive. The Ind[illegible]

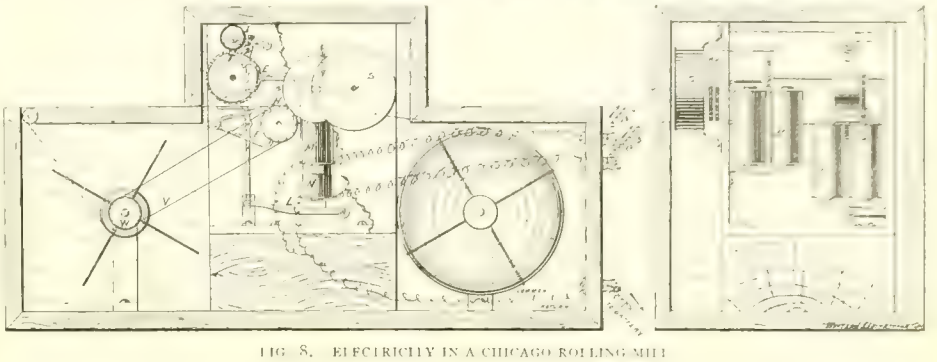

FIG. 8. ELECTRICITY IN A CHICAGO ROLLING MILL

to have mixed things somewhat, for he wrote: "Already 100 000 square feet of space have been asked for, and more than 41,000 feet of steam and electric current." Chief Barrett will soon make another eastern trip, starting about August 8th or 9th. He will attend the firemen's convention at Springfield, Mass., and also pursue his missionary labors among eastern electrical companies.

Before long Secretary Hornsby will issue diagrams of the main and gallery floors of the electricity building, showing the proposed location of the aisles and the arrangement of the space. These will be sent to the applicants for space, with the request that they indicate the location they would prefer. It will be impossible, of course, to comply with the desires of exhibitors in this respect in all cases, but it is thought that the replies will be of much service in apportioning the space available. Wherever practicable, the wishes of exhibitors as to location will be complied with.

A tool house has already been erected on the site of the electricity building, and the work of putting in the foundations will be begun at once. A spur from the Illinois Central railroad runs alongside the site of the building, greatly facilitating the shipment of material.

The Sperry Electric Mining Machine company of Chicago has applied for 1,250 square feet of space in the mining building.

One of the unique features of the fair, if the proposition of the Pittsburg Reduction company is accepted, will be a complete 125 horse power plant for the production of aluminum, all the processes for the reduction of the much-talked-about metal by electricity being performed on the spot. For this purpose a current of [illegible] amperes at 50 to 60 volts will be necessary. The Reduction company will gladly accept the current from the big power house, or it will set up two dynamos of its own if power is furnished to run them. This exhibit, although partly electrical in character, will [illegible] mining department, being [illegible] or in a small building of [illegible]

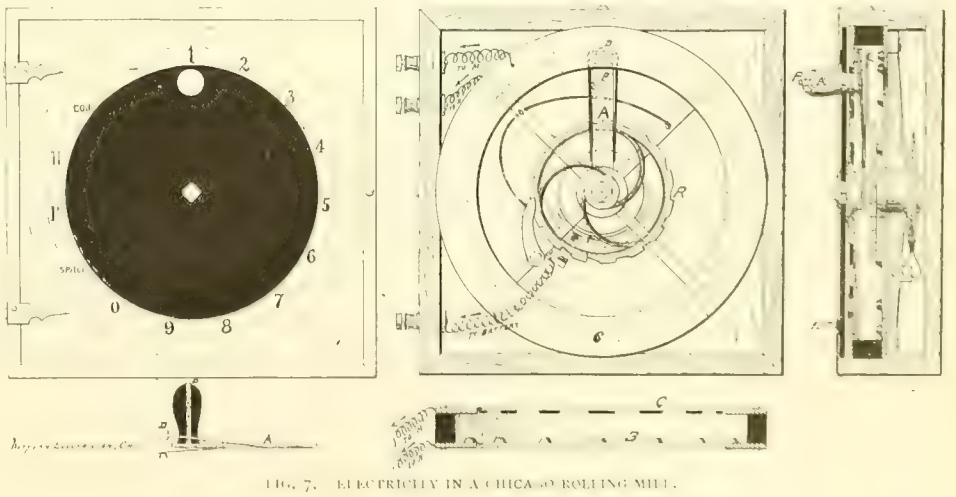

FIG. 7. ELECTRICITY IN A CHICAGO ROLLING MILL.

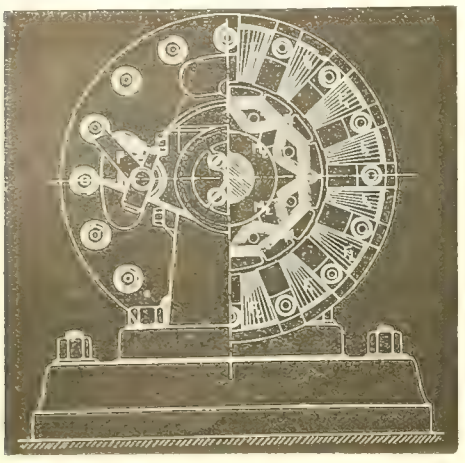
The Hubin-Leblanc Alternating Current Motor.

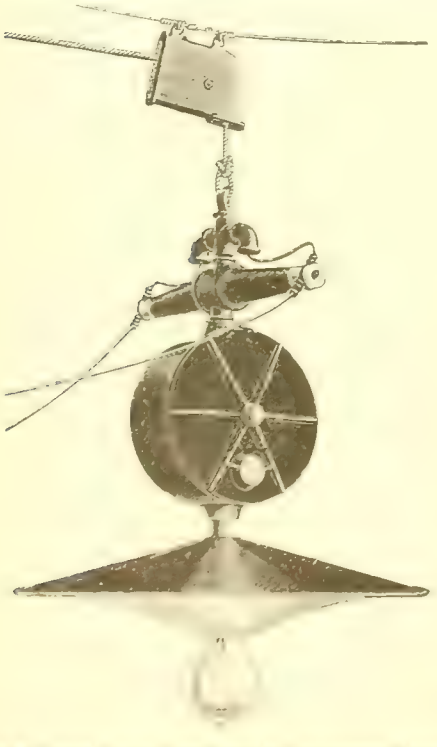
In the accompanying illustrations is shown the new Hubin-Leblanc alternating current motor, built by the Societe L'Eclairage Electricite. This motor is claimed to possess several advantages.

The cuts represent a 15,000 watt machine, the main features of which are a double ring of electric magnets. The outside part of the ring is immovable and constitutes the field, while the inside ring is mounted on a rotating



THE HUBIN-LEBLANC ALTERNATING CURRENT MOTOR.

shaft and forms the armature. The core of the outside ring or field is built of a large number of sheet-iron disks, insulated from each other and bolted together in the usual way. These disks are furnished with 16 double notches, in such a way as to form sixteen grooves both on the outside and inside of the cylinder. Room is thus made for two sections of windings, F_1 and F_2, each of which has 8 spools, filling the entire space of the notches. The outside part of the armature has a laminated core, securely fastened to the shaft and also furnished with 16 notches in which the armature wire is placed. The construction is similar to that of the outside ring, there being two sections, each composed of 8 spools joined together in series. One side of these two sections is joined together with the



The speed of the motor is 1,100 revolutions per minute, but by increasing the speed to 1,800 revolutions per minute, which can be done without danger to the windings, the efficiency increases to 88 per cent. The length of the iron core in the outside ring or field is 1.31 feet; the inside diameter is 0.98 foot. The size of the wire is equal to No. 13 B. & S. gauge and the number of windings per spool is 42. The resistance of the windings on the outside ring is 7.8 ohms when all the spools are joined in series and 1.97 ohm when joined in multiple series. The resistance of the armature is 0.18 ohm.

The motor has been subjected to a series of trying experiments and has stood the test successfully, according to the *Elektrotechnischer Anzeiger*, from which the cuts are reproduced.

The National Series Transformer System for Street Lighting.

Of the many problems met with in electric lighting by means of the alternating current, probably none taxes the ingenuity of the electrical engineer so much as the illumination of streets or other large areas by means of transformers. As a rule, the lights are several hundred feet apart, and to run a secondary circuit from a transformer centrally located would, of course, be highly uneconomical and comparatively expensive. Various arrangements to overcome this difficulty have been proposed and put into practice. Taking a 1,000 volt current as a standard, 40 25 volt or 20 50 volt lamps may be connected in series, but this arrangement would necessitate some sort of an automatic device for keeping the circuit closed, should one or more lamps in the series become disabled. It would also be necessary to provide means of guarding against the increase in voltage at the remaining lamps.

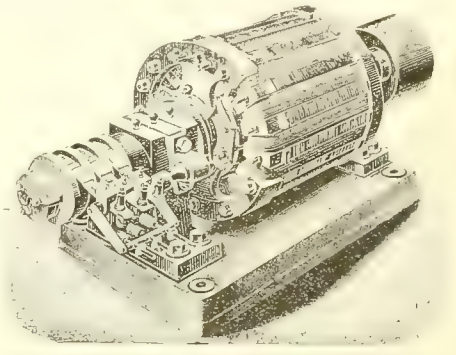
To overcome many difficulties and to provide a system of lighting which will be at once simple, reliable and efficient, the National Electric Manufacturing company of Eau Claire, Wis., has just put upon the market a special series transformer illustrated in the accompanying cut. These transformers do not materially differ from the company's standard transformers except in the ratio of winding between the primary and secondary coils, which is one to two, as against one to twenty in the regular transformers. The primary coils are wound for 100 volts and the secondaries for 50 volts, with a suitable allowance for loss in the circuit. Thus ten of these transformers can be connected in series on a 1,000 volt circuit, absorbing 100 volts each in their primary coils, with a difference of potential of 50 volts at the secondary terminals. The secondary coils are wound with wire large enough to carry up to three amperes of current without heating, and consequently a change of lamps to those of other candle powers can be easily accomplished.

The proportion between primary and secondary coils and the core of the transformers is such that, should the lamp become extinguished, the transformer becomes a [illegible] but other similar devices only lowers the electromotive force of the circuit sufficiently to make up for the [illegible] lamp, and it is claimed so nearly perfect [illegible] that from one to eight [illegible] of ten, without appreciably increasing the candle power of the remaining lamps.

[illegible] are placed in an iron weather [illegible] with a light cross arm and depending [illegible] carrying the reflector canopy, [illegible] and lamp socket. The secondary wires are entirely inclosed, while the primary terminals are carried through a T shaped pipe to the cross arm, the whole arrangement being preferably suspended at street intersections similar to arc lights. The transformers can, however, be provided with a gas pipe bracket for attachment to lamp posts direct.

Hercules Electric Motor.

The accompanying cut illustrates a new motor which is placed on the market by the Zucker & Levett Chemical company of New York. As can be seen, the motor is of the inverted horseshoe type, in which the whole of the mag-



THE HUBIN-LEBLANC ALTERNATING CURRENT MOTOR.

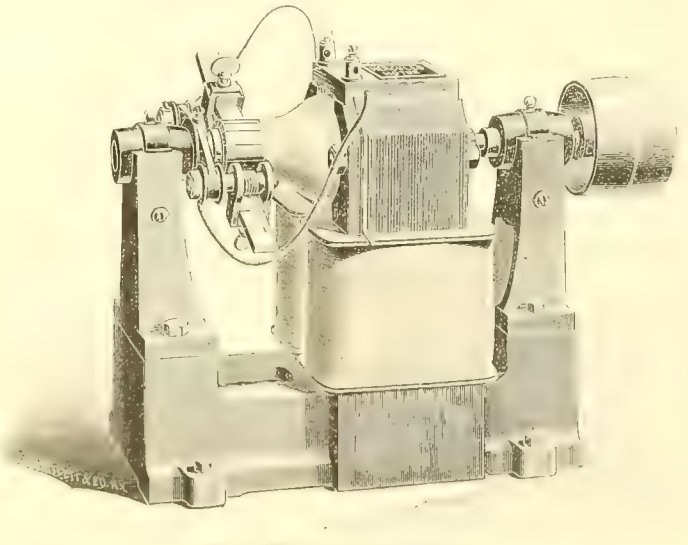
netic circuit is stamped out of one sheet of Swedish iron, the number of sheets being bolted together to form the magnet frame.

The plates are thoroughly insulated to prevent the generation of Foucault currents and consequent heating. The field coils are separately wound on brass spools and the distance between the magnet cores is slightly larger than twice the depth of one coil, thus allowing the coil to be slipped over the core.

The plates of the armature, which is of the modified Siemens type, have teeth forming longitudinal channels on its periphery, in which the coils are wound. These teeth, beside reducing the magnetic resistance to a minimum, entirely prevent the coils from flying out, due to the centrifugal force, and consequent burning out of the armature.

The magnet frame is bolted to an iron base, having iron standards and self-oiling bearings even in the smallest size of machines.

The automatic motors are mostly shunt wound with an armature of extremely low resistance. The fan motors are series wound and run a six blade 12-inch propeller fan at



THE HERCULES ELECTRIC MOTOR.

1,600 revolutions per minute, taking one ampere at 120 volts.

The mechanical details of these machines have been very carefully worked out, and all parts are adjustable. Quite a number of the Hercules fan outfits are in daily use. These machines will be manufactured in all sizes from one-eighth horse power up for both light and power

Chicago City Lighting Plant.

While Prof. Barrett was in Fort Wayne last week he purchased two 60 light Wood arc dynamos for use in the northwestern station of the city lighting plant of Chicago. Four systems—the Thomson Houston, Brush, Western Electric and Fort Wayne—are now represented in the several street lighting stations of the city

Richardson's Electrical Impression Indicator for Printing Presses.

Attention has been called to an electric indicating device invented by G. B. Richardson and applied to the press of the David C. Cook Publishing company of Elgin, Ill.

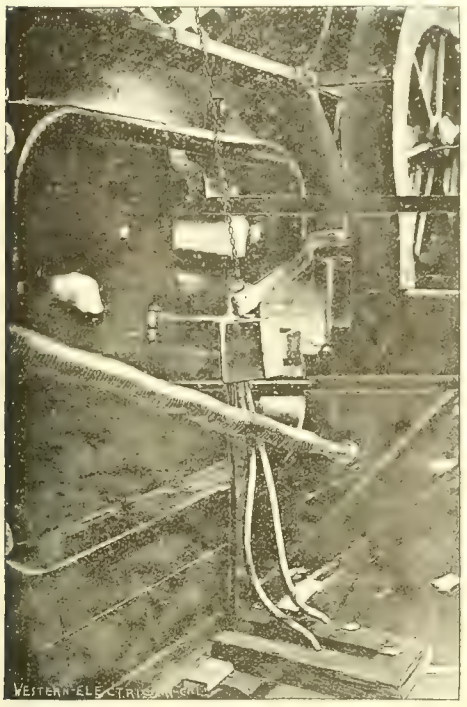


FIG 1. RICHARDSON'S ELECTRICAL IMPRESSION INDICATOR FOR PRINTING PRESSES.

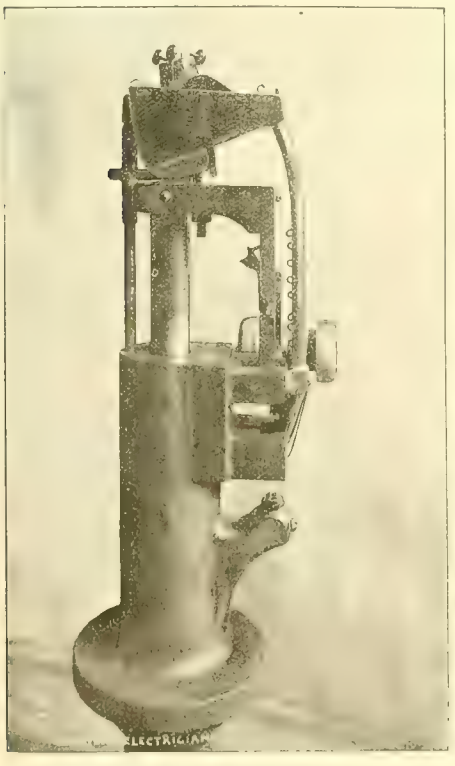
The device has attracted more than usual attention owing, no doubt, to its simplicity. It is illustrated in the accompanying views and will be readily understood. The whole arrangement is simplicity itself. A push button at the press, operated by a lever, Fig. 1, so connected to a moving part of the press that one contact is made for every impression; a row of lamps in a case in the office, Fig. 2, and each lamp connected by a separate circuit to a button on a press; the whole drawing current from the 110 volt Edison house-lighting circuit—this is the outfit through which each press indicates at the desk of the manager its every impression.

Magnetic Button Fastener.

An ingenious application of an ordinary horseshoe magnet in a mechanical appliance is shown in the illustration. The machine, which is the invention of Clyde and Clarence Coleman of Chicago, is designed for the purpose of affording a rapid means for attaching buttons to shoes. The difficulty was to devise some simple plan of feeding the buttons from the hopper on top of the machine down the tube leading to the stamping mechanism. This is effected by the magnet, which, playing up and down in the hopper through a slot in the bottom, attracts several of the loose buttons at each upward movement. In the picture the magnet is shown at its highest point, with buttons clinging to it. On the downward stroke the buttons are rubbed off into a little trough adjusted to fit the magnet closely. This trough is so grooved that the buttons, naturally attached to the magnet by the iron wire forming the eyes, fall into the chute in the proper position, as shown in the illustration.

FIG. 2. RICHARDSON'S ELECTRICAL IMPRESSION INDICATOR FOR PRINTING PRESSES.

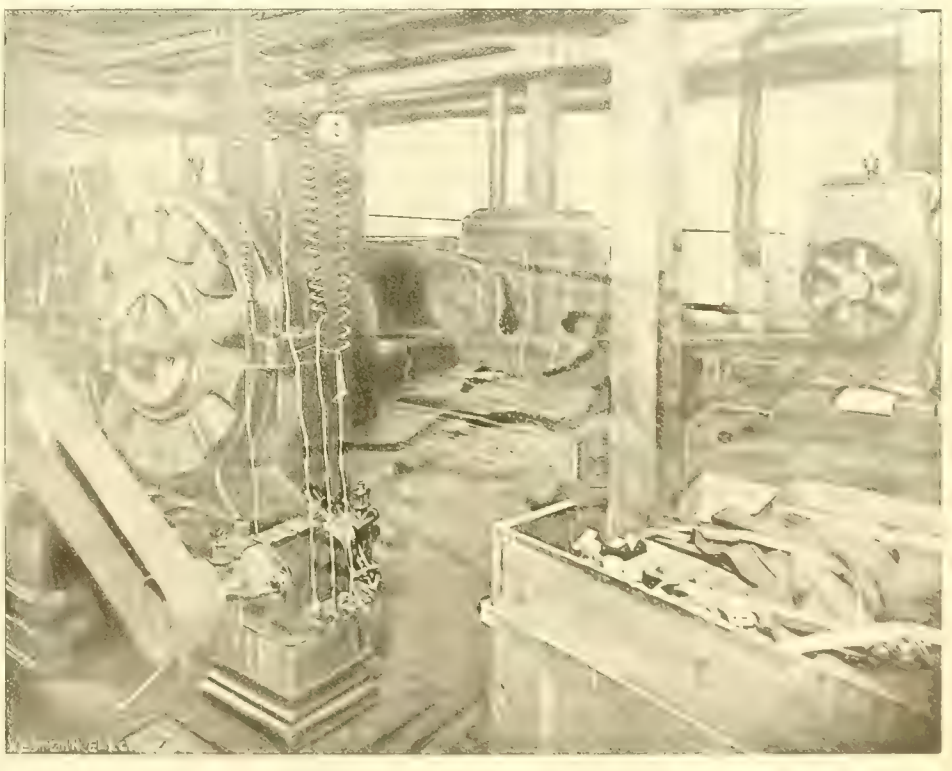
At the bottom of the chute the wire fastening is fed through the eyes of the buttons from a coil at the right hand of the operator. The wire is cut off at the proper length and stamped through the leather, which is, of course, held in position by the person operating the machine. The wire is formed into a staple and clinched on the under side, and the shoe is then adjusted for another button. The machine is operated by treadle, and all movements necessary for fastening one button are made by one downward tread.



MAGNETIC BUTTON FASTENER.

Lighting Plant at the Allen Flats, Chicago.

Chicago is blessed with many fine apartment buildings, or "flats," as they are more generally called, although, of course, this style of residence has not such an enforced popularity as in pent-up New York, for instance. As a type of this class the new Allen flat building on Oakwood boulevard, near Cottage Grove avenue, may be taken as a fair representative. It is typical in its handsome and imposing exterior, in its comfortable, almost luxurious, fittings, and in the character of its tenants. Here are pleasantly fitted suites forming either the homes of contented and happy families or the comfortable bachelor quarters of single gentlemen. Among the latter are many professional men; and not a few journalists, attached either to the daily or technical press, find in flats such as the Allen a congenial



LIGHTING PLANT AT THE ALLEN FLATS, CHICAGO.

the neighborhood of Cottage Grove avenue in the district bounded on the north and south by 35th and 39th streets. The arc lamps are used largely for lighting stores. The wiring is overhead, except at the street crossings, where the city ordinances require the conductors to be buried. In running the lines, the wires are carried across the streets in wrought iron pipes driven through from cellar to cellar.

The electrical apparatus in the station consists of two arc light and one incandescent machine. The incandescent dynamo is a 650 light separately excited Slattery alternating current machine. The arc lighting equipment consits of two 60 light Wood dynamos. These machines are driven by a 100 horse power New York safety engine. The two arc machines are belted in tandem to one side of the engine and the alternator is driven directly from the other fly wheel. The building is wired for 800 lamps, which are supplied through converters. The transformers are mostly twenty-five lighters, and they supply fifty volt lamps.

Electric Road at Bloomington, Ill.

There is a limit to human endurance, and it appears that this limit was reached by the members of the city council of Bloomington when at their last meeting a resolution was unanimously adopted declaring forfeited the franchise of the Bloomington and Normal Street Railway company. The members seem thoroughly tired of the present street car service, which has been execrable for many months. It is understood that [illegible] several capitalists are ready to [illegible] and efficient electric road.

Medical Lighting Apparatus.

Additions are daily being made to the already large number of electro-medical appliances. The accompanying illustrations show a new device for throwing light into the cavities of the human body. The little apparatus consists essentially of a lamp provided with a sheath made to fit the finger. It has a spring contact so arranged as to open and close the circuit as the finger is bent or

MEDICAL LIGHTING APPARATUS.

straightened. This attachment is the invention of P. Oudin and H. O. Kratz-Boussac of Paris.

Evanston's Electric Railway.

A company has been formed to build an electric railway at Evanston, Chicago's most attractive suburb. The corporation will be known as the Chicago & Evanston Electric Railway company, and the capital stock is $500,000. The incorporators are John L. Cochran, DeLancey H. Louderback, Frank S. Gorton and Alexander Clark.

One of the projectors of the enterprise is authority for the statement that the Edison interests would support the project. It is proposed to at once apply for a franchise to construct a double track electric road with the overhead system. It will extend through the villages of Evanston, South Evanston and Rogers Park, and connect with the Lincoln avenue cable. A portion of the route will be through Evanston avenue north from Lawrence avenue to the city limits, thence west on Homan street to Clark street and north on that thoroughfare through the township of Evanston.

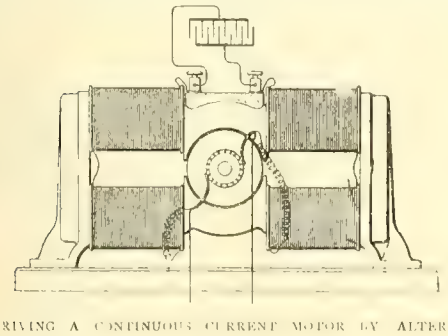
If a satisfactory arrangement cannot be made to transfer passengers from the southern terminal of the electric road to the central portion of the city, the line will be extended further south. The line will be thirteen miles in length and will afford 17,000 people an opportunity to visit the city without inconvenience.

Driving a Continuous Current Motor by Alternating Current.

A method through which it is proposed to render practicable and efficient the operation by an alternating current of an electric motor of ordinary type is illustrated in the accompanying diagram. The arrangement, which was devised by W. Stanley, Jr., of Pittsfield, Mass., and J. F. Kelly of New York, is claimed to be such that the motor may have the full capability of starting and regulation common to the corresponding forms of continuous current motors.

The particular form of motor to which the method applies is one having a commutator, and a field circuit in shunt to its armature circuit.

The invention is based on the well-known property possessed by a condenser of neutralizing or counteracting the



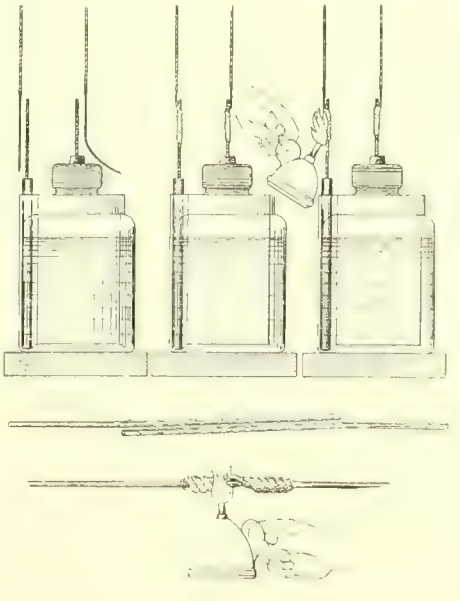
DRIVING A CONTINUOUS CURRENT MOTOR BY ALTERNATING CURRENT.

effects of the self-induction of a circuit with which it may be connected. The arrangement consists in the combination, with a motor of the kind illustrated, of a condenser included in the field circuit, or, in other words, in that circuit having the higher self-induction.

According to the inventors, if a motor of the kind described be operated by an alternating current, a loss is occasioned by the high self induction of the field circuit, which retards the phase of the current-imparting magnetism to the field magnets. As a consequence the maximum magnetic effects of the armature and field are not coincident, a condition which impairs the efficiency of the motor. In order to counteract this, and to bring the maximum magnetic conditions of the two elements, armature and field, more nearly into coincidence, there is introduced into the field circuit a condenser, which has the effect of bringing the phase nearer to that of the impressed electromotive force of the generator. The efficiency and economy of this disposition will, of course, depend upon the electromotive force, rate of change of the current, and other well understood conditions. In practice the cores of the field magnets should be laminated. A glance at the cut will enable the reader to understand the connections.

Method of Making Reliable Joints in Battery Wires.

In telephone work particularly it has been found that the mode of making battery connections by means of binding screws is unreliable. After but a short period of use, owing to the creeping action of the salts, corrosion takes place at the contacts, and the resistance of the circuit is largely increased. From the fact that as a rule a telephone battery is included in a short office circuit, any undue resistance is more serious than it would be were the connections of greater resistance. It becomes, therefore, a matter of vital importance to keep the resistance of the battery circuit at its lowest possible point, and on this account the method of forming joints on the wires which is



METHOD OF MAKING RELIABLE JOINTS IN BATTERY WIRES.

illustrated herewith will be of interest to the practical reader.

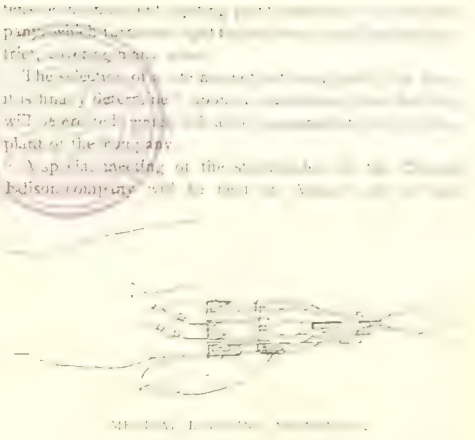
To make a battery connection there are provided terminal wires, each having one of its ends moulded into the plates as indicated. The other ends are coated by dipping with easily fusible alloy. To make a connection with other wires—say those of a Blake transmitter—it is only necessary to wind the wires from the transmitter round the battery wires as shown in the cut, and then direct upon the splice a moderate amount of heat—that of a small lamp being sufficient. Perfect battery connections, it is claimed, may thus be formed with great facility.

H. V. Hayes of Cambridge, Mass., and A. S. Hibbard of Morristown, N. J., are joint inventors of this device.

Chicago Edison Company.

As has already been stated in the WESTERN ELECTRICIAN, the Chicago Edison company has under consideration several propositions involving a change of location for its offices. The latest proposition, and one, which appears to be received with considerable favor by the directors, is the removal of the Adams street central station to a point near the river. This would enable the company to materially change the plant so as to effect a great saving in the cost of operation. The present headquarters of the company on Adams street are in the center of the business district of the city, but the contemplated change of site would not prove a disadvantage. The officers of the company say the plans have not yet progressed far enough to warrant a definite announcement of their arrangements.

The ground which the company's building now occupies has a frontage of 45 feet, and is leased for a period of 99 years at a rental of $8,000 a year, the lease having 95 years yet to run. The building is three stories high and was erected three or four years ago, the design providing for a high office structure which has never been completed. The company's offices are located here and also the ex-



action regarding the proposed increase of capital stock from $750,000 to $1,000,000.

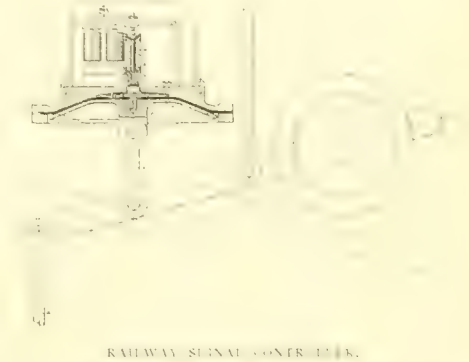
Firemen Aided by Electricity.

Electric cars were put to a new use in Oak Park, Ill., near Chicago, a short time ago. An alarm of fire had been sounded, and the village hose cart came bounding and plunging down the street just as a Cicero and Proviso electric car passed the corner. But the roads were bad, and the firemen were making slow work of it, while the red glare of the burning building half a mile or so away warned them that no time was to be lost. The conductor of the car took in the situation at a glance. "Hook on your old cart behind the car," he shouted. The firemen gladly availed themselves of the invitation, and the apparatus was whirled along to the scene of the fire in a twinkling, thus demonstrating another of the manifest advantages of electric traction.

Railway Signal Controller.

There are many electrical devices for operating railway signals, but the accompanying illustration shows one in which the idea has been worked out in a new way. By means of this device the signal may be operated from a tower some distance away, or it may be used where it is necessary for each train to put the signal to danger on passing an electric contact.

In the illustration *e* is the usual balance lever, weighted so as to put the signal to danger in case of a rupture of the connections; *n* is the connection which extends to the adjacent tower, and *s* is the rod which is in direct connection with the signal. The cut shows the weight lifted and the signal at all clear. The balance lever is centered on a link *d*, which is fastened to the diaphragm *r* by the buffet *t*. When the valve *b* is closed by means of the electro magnet pushing down the valve stem *a* the diaphragm is held in the position shown by the atmospheric pressure, and consequently the signal may be operated at will by the man operating the mechanical connection. But should the man operating the circuit in connection with the magnet open that circuit, then the spring *c* is released and raises the valve stem about one-sixteenth of an inch. The



RAILWAY SIGNAL CONTROLLER.

air is then allowed free access to the diaphragm chamber and the diaphragm falls to the dotted position [illegible] and the signal is thus put to danger. In the same manner the man operating the electric circuit may prevent the lowering of the signal at any time. The magnet is shown as working on a normally closed circuit, but in certain cases it may be desirable to work with a normally open circuit. Instead of the diaphragm a piston or valve might be used, but there is less danger of leak with a diaphragm. The device is the invention of A. H. Johnson of Orange, N. J. The cut was taken from the [illegible]

Reorganization of Westinghouse Interests.

At the adjourned meeting of the Westinghouse Electric & Manufacturing company at Pittsburg, July 15th, the plan of reorganization as outlined by Mr. Westinghouse's statement on April 7th was formally adopted, and a new board of directors was elected. The meeting was attended by a large number of stockholders. George Westinghouse, Jr., the president of the company, after calling the meeting to order, made the following statement: "I have pleasure in stating that the plan of reorganization has met with the approval of the holders of over 95 per cent. of the stock of the company. The reorganization committee has closely examined the books, and looked into the affairs of the company generally, and it has announced that it is satisfied with the condition of affairs and is willing to become a part of the board, and is ready to carry out the plans of reorganization upon the lines agreed. Brayton Ives, chairman of the committee, is here to-day to vote the stock deposited with the Mercantile Trust company."

Resolutions necessary to perfect the reorganization were then presented. The main points in the resolutions were: In the plan of reorganization, as announced on April 7th, $4,000,000 of cumulative preferred stock to bear 7 per cent. interest is created, $3,000,000 of which has been taken at par by the reorganization committee. This it is proposed to utilize in arranging for the floating debt of the company and providing for additional working capital. The assenting stockholders, who gave up the required 40 per cent. of their holdings of the original common stock, aggregating $2,500,000, for value, which had been turned over to the Mercantile Trust company of New York for the use of the company, are to receive a 7 per cent. preference on the 60 per cent. of their original stock retained, over the small amount of non assenting stockholders now withheld from the reorganization committee.

There were 141,402 shares of stock voted, which includes the stock voted by Brayton Ives, chairman of the reorganization committee. The following board of directors was elected: August Belmont, Henry B. Hyde, Marcellus Hartley, George W. Hebard and Brayton Ives, all of New York; Charles Francis Adams and Charles Fairchild, both of Boston; George Westinghouse, Jr., A. M. Byers and Lemuel Bannister, all of Pittsburg.

The meeting was then adjourned until July 29th in order to make necessary arrangements for the adoption of the plan of reorganization. The result of the meeting was favorably commented on in financial circles, and the newly elected board of directors is highly regarded for the financial standing and business sagacity of its members. The men at the head of the concern are all of national reputations, thorough business men and able financiers, and with the large amount of capital now at their disposal there is no doubt that the company will once more become an important factor in electrical matters.

The Montreal Convention.

The citizens' committee of Montreal is pushing forward the completion of the plans for the entertainment of the National Electric Light association with the vigor for which the people of that city are noted. The corporation of the city has just voted the appropriation of a large sum of money to be placed at the disposal of the citizens' [illegible]

The use of quite a number of yachts has been tendered by private gentlemen of Montreal especially for the pleasure of the ladies attending.

President C. R. Huntley of the association announces [illegible] hoped that, as suggested by the executive committee, which will add to the interest [illegible] information on the details [illegible] operation of central station [illegible] will be placed at headquarters in Montreal for the reception of written [illegible] [illegible] will be [illegible] open [illegible] [illegible] [illegible]

Incandescent Lamp Litigation.

The decision of Judge Wallace in the case of the Edison Electric Light company against the United States Electric Lighting company was announced in the last issue of the WESTERN ELECTRICIAN.

Considerable interest was of course manifested is this decision, involving as it does, the control of the entire incandescent lamp business. It is probable, however, that an appeal will be taken, although as yet notice of appeal has not been served. Eugene H. Lewis, of Eaton & Lewis, attorneys for the Edison company in the recent hearing, was in Chicago last Monday. To a representative of the WESTERN ELECTRICIAN he said that while there had been no notice of appeal as yet, the Edison company anticipated further litigation. "However," he added, "Congress could not have enacted a law more fortunate for us than that passed at the last session establishing a court of appeals at New York. According to that act any patent decision rendered after July 1st must be appealed to this court. It so happened that the decision in the Edison case was the first patent case decided after July 1st, so that if the case is appealed it will be heard in the new court early in October instead of waiting its turn for three or four years in the Supreme Court. Thus, if the case is appealed, we will get an early decision, and one whose benefits will not be modified by delay."

G. O. Fairbanks, Chicago representative of the Westinghouse Electric & Manufacturing company, said that he knew absolutely nothing about the case or decision beyond the facts given in the papers. "This decision will affect other companies as well as ours," he said. "It will stop the manufacture of many lamps; the case will probably be appealed."

F. S. Gorton of the Chicago Edison company said: "I have always pinned my faith, and incidentally my spare cash, to the Edison company, knowing that this decision would eventually be rendered." Concerning the companies opposed to the Edison interests, he added: "These companies have been playing a game of bluff and saying that this thing didn't amount to anything They have gone ahead manufacturing new lamps regardless of patents and points of law. Now the court has decided against these pirates, and they must stand the consequences."

"Will the case be appealed?"

Mr. Gorton scowled darkly at the windows of the Westinghouse company, whose offices are across the street in the Rookery building, and expressed the opinion that it would be appealed, but to no purpose.

B E. Sunny of the Thomson-Houston Electric company said that the decision was one that they had been expecting and helping to bring about as far as possible. "This decision will do away with poor lamps," he said, "and will put an end to the manufacture of lamps by those who don't know how to manufacture them."

F. S. Terry, manager of the Electrical Supply company, Chicago, when questioned about the recent decision in the lamp case replied:

"I have not given especial attention to the matter, but we have been and still are selling incandescent lamps."

"But what effect do you think this decision will have upon the trade?" he was asked.

"I have not considered the matter very fully, but if the Edison company pursue the policy which I understand is contemplated, it ought to be to the advantage of all large concerns engaged in making or selling incandescent lamps. The 'wild-cat companies' and 'curb-stone dealers' have succeeded in reducing prices to a point at which no profit can be made by the manufacturer or dealer, and if the Edison company will put prices up, and then make all the manufacturers preserve a uniform scale, and pay it (the Edison company) a reasonable royalty, the result will be profitable to all, and certainly bring an immense return to the Edison company."

"But what about the litigation which is likely to follow?"

"If the Edison company pursue this policy, there will be no litigation, as all the manufacturers and dealers will, in my opinion, gladly acquiese, and find, besides, that they are benefited after they are well over the smart of having to pay some damages. If, however, the Edison company should attempt to stop manufacturers and dealers from making and selling lamps, I think a desperate, expensive and long drawn out fight would follow, certainly lasting until the patent expires, which I understand will be in about two years. You can see, of course, that any attempt on the part of the Edison company to close the lamp manufacturers would necessarily result in a combination of lamp and machinery manufacturers, as well as dealers, against the Edison company. The Edison policy of raising prices, keeping them uniform, and levying a royalty from other manufacturers, meets my approval, and in view of the court's decision, I think that substantially all of the people interested in this branch of the business will cheerfully support the Edison company in that policy."

"But suppose the Edison company should succeed in stopping the manufacture of other lamps, notwithstanding the fight which you think would be made, what course would you take then?"

"I do not believe the Edison company will attempt such a thing, as it seems clear to me that such action could not possibly be the most profitable course for them to pursue, nor do I think they could close up the manufacturers during the life of the patent, even if they wished to do so. Such an attempt on their part would, in my opinion, stimulate invention and result in the development of a new lamp, entirely independent of the Edison patent. Indeed, I actually know of a person who, anticipating such a conclusion of the Edison suit, has been working for a year in the direction I mention, and has succeeded in producing a lamp, which proves to be entirely satisfactory and which does not use an exhausted globe. This lamp, I am assured, has passed successfully through every experiment, and I have every reason to believe it to be a thoroughly practical and successful article, and one that besides can be easily introduced should occasion arise."

Several of the managers of the local supply companies which were affected by the decision, declined to say anything for publication.

The opinion accompanying the decision is appended:

Two claims of letters patent, No. 223,898, granted Thos. A. Edison, January 27, 1880, for an improvement in electric lamps, are in controversy in this suit. These are claims 1 and 2. It is not asserted for plaintiff that the defendant infringes the other claims of the patent, consequently they will require no attention further than to see whether their terms may assist in defining the meaning of the claims in litigation.

The plaintiff contends that these claims are for fundamental inventions of great merit, and are entitled to a construction by which every incandescent lamp for electric lighting, consisting essentially of a filamentary carbon burner, hermetically sealed in a glass vacuum chamber, is within their terms. The defendant contends that unless the claims are limited to narrow inventions, not employed by the defendant, they are invalid for want of patentable novelty. The questions of the validity and scope of the patent have been adjusted in the courts of England and Germany with a diversity of opinion by the judges who have considered them. The specification is a perplexing one. The difficulty lies in its shadowy demarkation of the line between the essential and non-essential features of the invention described. It catalogues a number of discoveries which Mr. Edison had made; it sets forth some of the essential features of the lamp, and then it leaves to be found by inference from generalities what the elements are of the combinations included in the extremely elastic terms of the two important claims.

Nevertheless, when a sufficient knowledge of the prior state of the art to which it relates has been acquired, the new departures from the old devices which it describes, and which, presumably, the inventor proposed to incorporate into the claims of his patent, are reasonably apparent. The specification states that the object of the invention is "to produce electric lamps giving light by incandescence, which lamps shall have a high resistance so as to allow of practical subdivision of the electric current into numerous small units and their conversion into luminous centers." By practical subdivision is meant a distribution and division of the current and its conversion into lights comparable with those of ordinary gas jets, on a scale and under conditions of convenience and economy adequate to a system of illumination for domestic purposes in villages and cities analogous to that of gas. Prior to 1879 there was no method known by which this could be done practicably. The problem involved the perfection of devices for the proper distribution and regulation of the current as well as those for translating it into the light. No reference to the pre-existing devices for generating electricity, conducting it to the translating devices, or regulating its pressure and quantity, is necessary except to state that the principles governing the relation of the resistance of translating devices to the character of the circuit in which they are arranged, whether in series or in multiple arc, were well known to electricians, and had been applied in various forms of electrical apparatus. They were two well-known devices for converting the current into light—the arc lamp and the incandescent lamp. In the former the current is forced to leap an air gap separating two conductors, usually of carbon, and in overcoming the resistance of the air space heats the adjacent surfaces of the conductors and produces a light of great intensity. In the latter light is produced by the incandescence of an electrical conductor, a conducting strip of burner, placed in a continuous circuit through which the current passes and which develops heat by its resistance to the flow. The arc lamp was suitable for use in streets, open spaces and large halls but its light was too concentrated and powerful for the illumination of dwellings or of rooms of small dimensions. It was the generally accepted opinion of electricians that the hope of progress in the subdivision of the electric light was to be found in modifying the features of the arc lamp. The reason for this conclusion need not be mentioned; it suffices to say that Mr. Lane-Fox in England and Mr. Edison in this country seem to have been the only notable dissidents, and each of them had expressed the conclusion that subdivision might be accomplished by the incandescent lamp when provided with a conductor of high resistance and small radiating surface arranged in system of multiple arc. Lane-Fox had set forth the advantages of such a lamp in three patents granted to him in England, two in October, 1878, and one in March, 1879, and in a letter to the

[illegible] than for a single one, and the amount of current can be [illegible] resistance in the conductor permits the use of a weaker current, [illegible] energy is [illegible] small incandescent mass will radiate a moderate light, like the domestic lamp Electricians knew how to make conductors of high resistance [illegible] small radiating surface. They knew that with the materials of the same specific resistance the total resistance of the conductor could be varied by varying its length and cross section. They knew what materials were preferable and what processes of treatment to make conductors of high or low resistance.

If they had only known how to construct a lamp in which the conductor would have adequate mechanical strength and durability for practical commercial use, while having the small radiating surface and high resistance desirable, there would have been nothing wanting and electric lighting by incandescence would soon have been an accomplished fact. Although Lane-Fox and Edison had contributed to the state of the art the recognition of the principle that the conductor must have high resistance and small radiating surface, and each of them had embodied the principle in lamps for which they had severally obtained patents, neither of them had invented a lamp which satisfactorily embodied all the conditions of success, because a burner of the necessary material, form and complementary adjuncts was yet to be devised. As to material, experiments had been tried with platinum, iridium and alloys of these metals, and with carbon of various kinds. It was known that platinum, being a poor conductor, could be readily brought to incandescence by the electric current, but to do so it was necessary to raise a temperature very near the fusing point, and a minute increase would melt it. On the other hand, carbon was known to possess at an equal temperature much greater power of radiation than platinum, but the difficulty was that it would combine with oxygen at high temperature and rapidly disintegrate. It could only be used, therefore, in a vacuum, which is practically unattainable. From the earliest lamp (disregarding the Geisler tube, because it has no burner in the true sense) patented in England by King in 1849, to the latest examples, like those of Lane-Fox or Edison's platinum lamp, patented in 1878 9, the history of the art shows a variety of experimeuts to perfect a lamp in which a carbon burner or a platinum burner would have sufficiently long life for practical requirements. The result of these experiments may be succinctly shown by quoting two well-known electricians. Mr. Schwendler, in an article published in 1879 in the *Telegraphic Journal*, said: "Unless we shall be fortunate enough to discover a conductor of electricity with a much higher melting point than platinum, and the specific weight and specific heat of which conductor is also much lower than for platinum, and which at the same time does not combine at high temperatures with oxygen, we can scarcely expect that the principle of incandescence will be made use of for practical illumination." Mr. Sawyer, in a patent to Sawyer & Man, granted in June, 1878, said: "At the present day it is not new to produce a light by causing the electric current to heat a carbon conductor to incandescence in a vacuum, or in nitrogen, or in other gas; but no lamp has yet been devised which would be practically operative, and for these reasons: First, the methods which have been adopted for charging the lamp with the artificial atmosphere, such as a displacement of mercury, water or air by the gas, or the combustion of phosporus in the lamp are imperfect. A perfect vacuum is unattainable. Some oxygen or other element or compound remains in the lamp, and slow consumption or disintegration takes place, for the remaining gas or vapor other than hydrogen or nitrogen attacks the carbon, which, in turn, is decomposed, with a result of depositing some carbon upon the globe and setting free the oxygen to attack fresh carbon. Second, it has been found practically impossible under the varying degrees of heat and pressure to maintain perfect joints, and the result is that expansion of the artificial atmosphere by the heat from the luminous conductor expels a portion of the same, and the contraction of the atmosphere upon cooling causes a portion of the external air to penetrate the globe, thus supplying oxygen which at the least lighting feeds upon the carbon. Third, the unequal expansion of the carbon and its holders has resulted in fractures of the former, so that, however perfect the atmosphere in the globe, the lamp has never been permanent."

The most advanced type of carbon burner lamps in 1875 were the lamps of Lodyguine or of Konn, and until the spring of 1879 lamps like those of the Sawyer [illegible] Man patent or the patents of Mr. Farmer. It was thought to be the merit of Lodyguine's lamp that it obviated the difficulty of the short life of the burner by using two burners, rods of diminished section at the luminous focus, on a glass receiver, hermetically sealed and filled with nitrogen, electrically arranged so that the current would be passed to the second carbon when the first had been consumed. Konn provided his lamp with five carbon burners in the form of rods or pencils, and devices for bringing them successively into circuit. In the lamp of Sawyer & Man the carbon burner was a rod [illegible] globe charged with nitrogen gas, and the globe and its stopper both of glass were held [illegible]

In the lamp of the patents granted to Mr. Farmer, in March, 1879, the burner was a carbon [illegible] filled with hydrogen or other analogous gas, and the globe was closed by a rubber stopper [illegible] the one described in Mr. Edison's [illegible]

patents of 1879, had any attempt been made to make the vacuum chamber wholly of glass with the parts sealed together by fusion, or to seal the conducting wires leading to the burner through the glass by fusion of the glass. The impracticability of maintaining a carbon burner under such conditions that it would be sufficiently durable has apparently so impressed those who were studying lighting by incandescence that as late as in the early part of 1879 both Lane-Fox and Edison were trying to perfect a burner of other material. Edison's burner in his French patent of May 28, 1879, was of platinum wire coiled upon a bobbin composed of an infusible oxide, and Lane Fox's burner in his patent of May 14, 1878, was of platinum-iridium alloy, or of spiral strips of metal surrounding a tube of glass, fire-clay, steatite or lime, with the surface of the metal strips covered with asbestos, or some vitreous material.

This cursory view of the prior state of the art is sufficient for an intelligent reading of the specification. The specification describes the general nature of the invention as follows:

"The invention consists in a light-giving body of carbon wire or sheets coiled or arranged in such a manner as to offer great resistance to the passage of the electric current, and at the same time present but a slight surface from which radiation can take place.

"The invention further consist in placing such burner of great resistance in a nearly perfect vacuum to prevent oxidization and injury to the conductor by the atmosphere. The current is conducted into the vacuum bulb through platina wires sealed into the glass.

"The invention further consists in the method of manufacturing carbon conductors of high resistance, so as to be suitable for giving light by incandescence, and in the manner of securing perfect contact between the metallic conductors or leading wires and carbon conductors."

The specification then recites that previously light by incandescence had been obtained from rods of carbon of one to four ohms resistance placed in closed vessels in which the atmospheric air had been replaced by gases that did not combine chemically with the carbon; that the vessels holding the burner had been composed of glass cemented to a metal base; that the connection between the leading wires and the carbon had been obtained by clamping the carbon to the metal; that the leading wires had always been large, so that their resistance should be many times less than the burner, and generally the attempts of previous persons had been to reduce the resistance of a carbon rod. It then points out the disadvantages of such a lamp, stating that it could not be worked in great numbers in multiple arc without the employment of main conductors of enormous dimensions; that, owing to the low resistance, the leading wires have to be of large dimensions and good conductors, and a glass globe cannot be kept tight at the place where the wires pass in and are cemented, and consequently the carbon is consumed because there must be almost a perfect vacuum to render it stable, especially when it is small in mass and high in electrical resistance; and that the use of gas in the receiver at the atmospheric pressure serves to destroy the carbon by attrition.

The specification then states in substance that the patentee proposes a new departure; that he has discovered that even a cotton thread properly carbonized and placed in a sealed glass bulb exhausted to one millionth of an atmosphere offers from 100 to 500 ohms resistance to the passage of the current, and that it is absolutely stable at very high temperatures; that if the thread be coiled as a spiral and carbonized, or if a fibrous vegetable which will leave a carbon resistance after heating in a closed chamber be so coiled, as much as 2,000 ohms' resistance may be obtained without presenting a radiating surface greater than three-sixteenths of an inch; that if such fibrous material be rubbed with a plastic compound of lampblack and tar its resistance may be made high or low, according to the amount of lampblack placed upon it; that carbon filaments may be made by a combination of tar and lampblack, the latter being previously ignited in a closed crucible for several hours, and afterward moistened and kneaded until it assumes the consistency of thick putty; that small pieces of this material may be rolled out in the form of wire as small as seven one-thousandths of an inch in diameter and over a foot in length, and the same may be coated with a non conducting, non-carbonizing substance and wound on a bobbin, or as a spiral, and the tar carbonized in a closed chamber by subjecting it to high heat, the spiral after carbonization retaining its form; that he has carbonized and [illegible] paper, and splint papers, coiled in various ways, also lampblack, plumbago and carbon in [illegible] and kneaded so that the [illegible] of various lengths and diameters; that each wire should be uniform in size [illegible] and cannot be [illegible] that if platinum [illegible] and the material [illegible] there is [illegible] between the carbon and platinum, and nearly perfect contact [illegible] appearance of the light, which on a plain wire is prejudicial, as it shows the least unsteadiness of the current by the flickering of the light, and if the current is steady the defect does not show."

The specification then gives directions for carbonizing the carbon thread in a manner to prevent its distortion, for blowing a glass bulb over it after it is formed, for exhausting the glass bulb, and for hermetically sealing the bulb when a high vacuum has been reached.

The claims are as follows:

"1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires as set forth.

"2. The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted, for the purpose set forth.

"3. A carbon filament or strip coiled and connected to electric conductors so that only a portion of the surface of such carbon conductors shall be exposed for radiating light, as set forth.

"4. The method herein described of securing the platina contact-wires to the carbon filament, and carbonizing of the whole in a closed chamber, substantially as set forth."

The specification is addressed to those who were skilled in the art to which it relates; who appreciated the advantages of arranging incandescent lamps in a system of multiple arc, and of providing the lamp with a burner of high resistance with small radiating surface; who knew how high resistance, both specific and total, is imparted to a conductor; who knew that the rods, pencils, or other forms of carbon burners previously used had not been designed to embody the principle of high resistance; who knew how desirable it was to maintain the burner in a perfect vacuum, or in gases that would exclude the oxygen; who knew what had been attempted and had proved impracticable in that behalf; who knew that such materials as are mentioned in the specification (even the tar-putty compound seems to have been used in one process) would compose a carbon of high resistance when subjected to a proper process of carbonization; and who knew how to practice proper processes for the carbonization of such materials.

Read by those having this knowledge, the radically new discovery disclosed by the specification is that a carbon filament as attenuated before carbonization as a linen or cotton thread, or a wire seven one-thousandths of an inch in diameter and still more attenuated after carbonization, can be made which will have extremely high resistance and be absolutely stable when maintained in a practically perfect vacuum. It informs them of everything necessary to utilize this discovery and incorporate it in a practical lamp. It describes, with the assistance of the recital in the second claim, as the vacuum in which the burner is to be maintained a bulb made wholly of glass, exhausted of air, sealed at all points by the fusion of the glass, and in which platinum leading wires are sealed by the fusion of the glass. It describes the materials of which the burner is to be made, and instructs them that the materials are to be shaped into their ultimate form before carbonization. It describes the use of platinum for leading wires, and a method of securing the leading wires and filaments, intended to dispense with clamping, which consists in moulding tar-putty about the joints and carbonizing the whole in a closed chamber. Besides stating that the resistance of the burner will be greatly increased and the radiating surface still be kept within moderate limits by coiling it in the form of a spiral, the specification states that by increasing the lengths of the filament coiled the exterior only will be the principal radiating surface, and greater steadiness of illumination will be promoted.

The first claim must be read with several limitations. The filament is to be made of carbon of high resistance; that is, as the experts agree, of high specific resistance. The filament is to be made as described, that is, the materials are to be of some of the kinds described, and are to be shaped in filamentary form and then carbonized. The filament is to be secured to metallic wires according to the method of the patent, because the claim implies the elements of a globe and metallic conductor arranged in circuit with the burner, otherwise the combination would not be operative, and it would have been needless to specify the securing of the metallic wires to the filament unless it was intended to insert into the claim the specific method of doing so emphasized in the specification.

The defendant does not infringe this claim, if for no other reason, because the leading wires in its lamps are not secured to the filament according to the method of the patent, that is, by cement carbonized in situ, by clamps such as the specification condemns.

The second claim is broad enough in its phraseology to secure the real invention described in the specification, and can be read consistently with its language so as to impart into it every essential limitation.

It was a remarkable discovery that an attenuated thread of carbon would possess all the long-sought qualities of a practical burner when maintained in a perfect vacuum. The extreme fragility of such a structure was calculated to discourage experimentation with it, and it does not detract in the least from the originality of the conception that previous patents had suggested that thin plates, or pencils, or small bridges could be used. The futility of hoping to maintain a burner in vacuo with any permanency had discouraged prior inventors, but Mr. Edison is entitled to the credit of obviating the mechanical difficulties which disheartened them, but what he did in this respect was a matter of old, secondary merit, and was no longer new in the art because he had a ready disclosed it in his French and English patents. What he actually accomplished was to unite the characteristics of high resistance, small radiating surface, the durability in a carbon conductor by [illegible] of extreme tenuity out of any such [illegible] and to the production, carbon [illegible] and properly arranged [illegible] wholly of [illegible] the leading wires entered, by the fusion of the glass. He was the first to make a carbon of materials and by a process which was especially designed to impart high specific resistance to it; the first to make a carbon in the special form for the special purpose of imparting to it high total resistance; and the first to combine such a burner with the necessary adjuncts of lamp construction to prevent its disintegration, and give it sufficiently long life. By doing those things he made a lamp which was practically operative and successful, the embryo of the best lamps now in commercial use, and but for which the subdivision of the electric light by incandescence would still be nothing but the ignis fatuus which it was proclaimed to be in 1879 by some of the learned experts who are now witnesses to belittle his achievement and show that it did not rise to the dignity of an invention.

The coiled form of the burner is only an alternative feature and is not a constituent of the second claim. It is the subject of the third claim. Nor is the bent form or any form other than the filamentary. It may be that in the haste which has always seemed to characterize Mr. Edison's effort to patent every improvement, real or imaginary, which he has made or hoped to make, he had not stopped to reflect when he framed his application for the patent that the filamentary burner would do its work just as well uncoiled as coiled, provided the same length and cross section were used. It is true that it is said in the general statement of the nature of the invention that the burner is so "coiled or arranged" as to offer high resistance and present a small radiating surface; but this description is satisfied by any arrangement, whether by coiling a considerable length in a small globe or using the same length uncoiled in a large globe, by which sufficient total resistance is obtained from a filament of small diameter. It certainly would not involve invention to omit the coiling and elongate the globe; hence, it is manifest that the invention described is the same thing essentially, whether the coiled form is used or not. The language is satisfied if the burner is filamentary and so arranged as to offer great resistance and slight radiation, without importing into it anything which is not of the essence of the invention. No precise limitation upon the maximum diameter of the filament can be defined from the specification or is required as an element of the claim. The specification mentions by way of illustration the threads of linen or cotton which become more attenuated after carbonization and the carbon wire which after carbonization would be from four to five one-thousandths of an inch in diameter, while the smallest rods of carbon previously known were about a millimetre in diameter, thus having a cross section fifty times as great as the carbon wires. It is to be implied from the suggestions in the specification that it is to have sufficiently high total resistance for efficient use when the lamps are arranged in multiple arc, and to be used with leading wires of fine platinum. The claim is not limited to a carbon filament made of non-fibrous material. The conductors of the claim are the platinum wires mentioned in the specification. The receiver is the vacuum described in the specification. The peculiar method of securing the conductors to the filament, made a constituent of the first claim, is not imported into the second claim. A more exact interpretation of the meaning of the claim than has thus been indicated is not necessary in the present case, because each of the three lamps representing the kinds used by the defendant embodies the invention of the claim as thus interpreted.

It is of little import what Mr. Edison or his patent solicitor may have thought about the meaning of the claim during the pendency of the application for a subsequent patent, or that Mr. Edison may have supposed a resistance as high as 100 ohms in the burner would be required for use with the means of distribution which he expected to employ with his system of lighting. There are many adjudicated cases in which it appears that the inventor builded better than he knew; where a patent has been sustained for an invention the full significance of which was not appreciated by the inventor when it was made. In the case of the Bell telephone patent there was great room for doubt whether the speaking telephone had been thought of by Mr. Bell when he filed his application for a patent, but the court said: "It describes apparatus which was an articulating telephone, whether Bell knew it or not." 88 Blatch., 532.

The nearest approach in the prior art to the invention of the second claim is undoubtedly the lamp of Edison's French and English patents with a platinum burner. It seems almost preposterous to argue that the substitution of the carbon filament for the platinum burner of that lamp was an obvious thing to electricians. It would have been probable if there had been such a thing as a filamentary carbon in the prior art. But the nearest approximations to it were the ribbon-shaped carbon burner of low resistance of Mr. Farmer (which was not a part of the prior art, but an isolated example known only to a select few) and the low resistance carbon rod burners of the patent of Sawyer & Man.

Undoubtedly the improvements that have been made in the art, such, for instance, as the method of electrical carbonization of the filament, since Mr. Edison's invention, have been of great value, and the perfected commercial lamp of to day is far superior to the one which could be made by applying to the description of the patent all the knowledge and skill then possessed by those to whom it was more particularly addressed. But as was said by Bowen, L. J., in the court of appeals in England, "The evidence shows that lamps made solely on the patent will and do succeed, although subsequent improvements have been engrafted on the original design." It is impossible to resist the conclusion that the invention of the slender thread or carbon as a substitute for the burners previously used opened the path to the practical subdivision of the electric light.

The questions which have seemed the most meritorious of those argued at the bar have now been considered. Others, to which no reference has been made, have not been overlooked, and may be dismissed without discus-

sion, and with the single remark that nothing which has been presented by the voluminous proofs and the exceedingly able and elaborate arguments of counsel seems to supply any valid reason for refusing to decree for the plaintiff. The usual decree for an injunction and accounting is accordingly ordered.

CORRESPONDENCE.

New York Notes.

NEW YORK, July 18. -That Judge Wallace would render a decision favorable to the Edison interests in the incandescent lamp litigation was pretty confidently looked forward to by the knowing ones in electrical circles. These knowing ones predicted that if the suit were thus decided Edison stock would go bounding up sky high. In this, however, they were wrong, as Edison stock, no doubt to the disappointment of many who were holding it for a rise, did nothing of the sort. On the day that the decision was given out the price ran up about seven per cent., but no higher, and since then there has been a slight falling off. At present the stock is only quoted at three or four points above par, and no further increase in price seems probable for the present.

The question of the actual present benefit to be derived by the Edison General Electric company from the decision affirming its monopoly depends chiefly on the character of its own treasury assets. Its most valuable rights to the introduction of the incandescent lamp are leased to minor companies; the Edison Electric Illuminating company, for instance, controlling the business in this city. These concessions have a long term to run, and would yield nothing to the parent company in the territory surrendered, but for the fact that the stock in the smaller companies was, to a considerable extent, taken up by the Edison General company in part exchange for the conceded rights. The Illuminating company, having the right to use the incandescent lamp on Manhattan Island, will be a great gainer by the decision. There has been considerable opposition built up by the alternating current people, in both the upper and lower parts of the city, and the competing companies will now have to pay the Illuminating company a royalty on the incandescent lamps they use. According to an official statement just issued the net earnings of the Edison Illuminating company during the six months ending July 1st were $152,000, against $99,000 for the corresponding period of last year, an increase of over 53 per cent. This is a striking proof of the general opinion existing among electrical men in New York that the business of the Illuminating company is governed by a thoroughly sound and progressive policy.

General interest in the electrocutions has died out very quickly, and it would have been even shorter lived, because, after all, the topic is a disagreeable one, had it not been for the prolonged howl of our "brainy, breezy, new sy" newspapers at being excluded from the death chamber. One of the coroners of this city achieved a little notoriety by threatening to hold an inquest on the body of Smiler. He announced his resolution to have the body exhumed for the purpose of making another autopsy, but desisted, on being curtly informed by the attorney-general that he had no authority whatever to make the investigation contemplated. The state physicians, congratulate Warden Brown, "on the completeness in all their details of the preliminary arrangements, on the uniform good order and decorum which prevailed during the trying ordeal, and on the resulting demonstration of the rapidity and painlessness of this method of inflicting the death penalty"—'congratulations" which, to say the least of it, are scarcely in good taste, any more than the use of the word is. The physicians also state that "the experience of to-day has proved to our satisfaction that this method is superior to any other yet devised." And that is the last that I shall write you about electrocution, I hope, for a long time to come.

Great interest is manifested here in the preparations for the approaching week's cruise and drill of the state naval militia, to which a number of electrical men belong. The squadron of evolution, numbering seven vessels in all, headed by the flagship Chicago, is now anchored in the Hudson river. Next week the squadron will proceed to the eastern end of Long Island Sound, where the naval militia will embark and be treated to a week's hard work in the shape of drills of all sorts. The volunteers will be taught by the regular ships' companies the handling of the large and small guns and the general work of clearing a ship for action. Target practice with the big guns and a night torpedo attack form part of the programme, and an invasion of Fisher's Island, the scene of operations, will wind up the manœuvers.

If the systems of rapid transit which New Yorkers hope some day to see at work in this unhappy, congested island prove to be no more rapid than the tedious deliberations of the Rapid Transit commission itself, the inhabitants of this city are doomed to grievous disappointment. The motto of the commission may be "slow and sure," but it would seem to be "slow and uncertain." A meeting was announced for yesterday, when it was supposed that the route for the east side would be made public, and that also a description of the plan of construction of the Broadway route would be given out. Nothing of the sort took place. An executive session only was held, and no decision was arrived at. Next week, say the commissioners, they will probably decide on both questions. They have met with much difficulty above the Harlem river, where the law prohibits the building of a surface road, and they are not yet settled in their opinion as to whether the line should be underground, elevated or depressed. At present the public is depressed, owing to the dilatoriness of the commission in handling the important business for which they were preparing themselves for so long before actually entering on their duties.

The victory of the trolley in Brooklyn in face of most determined and bigoted opposition is naturally received with mixed emotions by the inhabitants, official and unofficial, of that benighted city. The State Board of Railroad Commissioners came out flat footed in favor of the trolley, to the credit of their common sense, be it said. They hold that it does not increase the danger of fire; that it does not impair the appearance of the streets; that the danger of running over pedestrians and collision with vehicles is inconsiderable, and that the trolley system has decided advantages over horses. To all of which opinions electrical men will doubtless say, "Amen." Some of the Brooklyn city fathers do not agree with the railroad commissioners, and as it is left for them to decide at what speed the cars shall be run, and to approve the poles used for supporting the wires, they hope to make trouble for Mr. Richardson yet. That gentleman has had extended experience in dealing with local statesmen, and no doubt he will induce them to allow the cars to run at a reasonable rate of speed, and also to approve of the poles which he already has submitted for their inspection.

The learned president of the Board of Electrical Control last month caused that august body to pass a resolution declaring the bond of the Consolidated company forfeit because certain subways were not finished on time. He also threatened to confiscate the subways, which have cost a trifle of five millions and a half of dollars Mayor Grant's colossal piece of bluff has been ignominiously scattered to the four winds by the corporation counsel, who has notified the mayor that the board had no authority to pass any such resolution or take any such action, consequently the resolution is inoperative, and the board, through its president, has once more made a spectacle of itself. The board has ordered that all poles and wires in the district bounded by Third and Eighth avenues and Eighth and Fifty-ninth streets, should be removed within ninety days, but the corporation counsel has also informed the board that it has no power to order the removal of poles and wires in districts where no subways have been provided, so that a goodly portion of this order is inoperative also, as there are no subways in many of the streets in the district alluded to. During the first six months of this year 3,156 poles and 5,573 miles of wire have been removed by direction of the board.

The announcement of the appointment of the Council of the Society of Arts to act as the Royal Commission for Great Britain at the World's Fair has been very well received here. The commission has many noted names on its roll, beginning with the Prince of Wales, who takes a marked interest in exhibitions of all sorts. James Dredge, the well-known editor of *Engineering*, who has many friends in this country, is an active member of the commission. Among the noted civil and electrical engineers on the commission are Sir Frederick Abel, William Anderson, Sir Frederick Bramwell, Professor Dewar, James Forbes, Sir Douglas Galton, Professor Roberts-Austen, and W. H. Preece, the chief electrician of the postoffice telegraphs.

The Empire City Electric company, now in course of liquidation, has liabilities amounting to about $100,000. The company has lately been losing several thousand dollars a month, and O. E. Madden, the chief owner and financial backer of the company, at last decided to let it go into liquidation. The stock is now being sold by the receiver, Charles R. Beardsley, and the creditors expect to realize a large percentage of the amounts owing them.

W. I. H.

Pittsburg, Pa.

PITTSBURG, Pa., July 18.—The Department of Public Safety of this city has passed an ordinance directing that all street cars must come to a dead stop within twenty feet of every crossing of the streets in the lower or business portion of the city. The department was prompted to take

[illegible]

The board of directors of the Pleasant Valley Electric [illegible]

the last six months. This is the second of the electric street railway companies declaring a dividend since it [illegible] was [illegible] operated [illegible] expenditures and net earnings was presented: Receipts for the last six months of 1890, $168,526.55, and for the six months of 1891, $188,884.44, showing an increase of $20,357.89. Receipts for the month of June, 1890, were $27, [illegible].05, and [illegible], [illegible], $[illegible] of $5,953.30. The expenditures during the first six months of 1891 were $124,046.05, which shows the net earnings as $64,046.05.

The Second Avenue company of this city has decided to extend its line to Homestead, a distance of four miles. The history of this company will be of interest to street railway men. The Second Avenue Passenger Railway company is one of the oldest street railway companies in this city. It was one of the first to change from horse and mule equipment to the modern method of rapid transit, the electric motor. The Second avenue line was started by W. J. Burns, who is now general manager of the road. In 1876 Mr. Burns had a large number of stage coaches engaged at the Philadelphia Centennial exhibition, and when that celebration was over he anxiously looked around for a means of putting those coaches into service. He then obtained the right of way from the city of Pittsburg to run his coaches along Second avenue. The operation of these vehicles was continued for many years, but it was accompanied with but indifferent success. Mr. Burns was at last prevailed upon to sell his franchise, and the new management immediately laid tracks and ran a horse car line along Second avenue as far as Copperworks station, a distance of two miles from the starting point in the city. But if the coaches were a fallure the horse cars were even worse. The road, during the time it was operated by horses, did not pay half the running expenses, and the new owners very soon became disgusted with their property. Several times Mr. Burns was approached, and inducements were offered him to take the road back again. He at last, in association with Wm. Callary and several other Pittsburg capitalists purchased the horse car road. The new owners immediately transformed the entire road. They sold the old horses, pulled up the rails, and work was at once commenced building an entirely new roadbed, putting down new tracks, and in the meantime contracts were made for electric motor equipments for ten cars. The line was also extended as far as Glenwood, a distance of five miles from the city. The first electric motor equipments were furnished by the Thomson-Houston Electric company of Boston, and the operation of the road was begun in March, 1890. From the day on which the road was first operated by electricity the financial success has been assured. Additional cars had to be put on to accommodate the increased traffic, and it was decided to utilize the Westinghouse single reduction motor system, which had recently been brought out. The Westinghouse company secured a contract for six additional cars, which were equipped with the Westinghouse single reduction motor. One of these cars is equipped with the first single reduction motor manufactured by the Westinghouse company. It is a remarkable fact that, although these motors were considered only experimental, and had been contructed for the purpose of developing the single reduction system, they have been operated on that car uninterruptedly ever since. For a long time it was the first car to leave the shed in the morning, and the last to come in at night, running 140 miles per day. During the entire period of the operation of this car with these motors the cost of maintaining the electrical equipment of the car perfect has not yet amounted to one dollar. The company has since purchased a number of vestibule cars with Gilbert trucks, which are all equipped with the Westinghouse system.

As an illustration of the fact that the road has been eminently successful since it has been operated by electricity it is only necessary to state that in spite of the road having only been operated for a little over a year the company has already paid a dividend out of its earnings. Encouraged by this success the company is now engaged in extending its line from Glenwood to Homestead, Pa., a distance of about four miles. To do this the company has to build a bridge across the Monongahela river. In addition to this extension the company is also laying a branch line to Schenley Park, which will be a great feeder to the main line when finished. The building of this extension will also entail the necessity of erecting a bridge. John Murphy is the superintendent and engineer of the road. B. L. W.

Minneapolis, Minn.

MINNEAPOLIS, Minn., July 18.—A scheme to connect Lake Minnetonka with Minneapolis by better means of passenger transportation than now exists has been under way for several months, and it is now stated that it will probably be carried out next season. T. B. Walker, a wealthy citizen of Minneapolis, and Cal. Goodrich, superintendent of the Minneapolis street railway system, have extensive property interests in the western suburbs of the city and in the vicinity of St. Louis Park, which lies geographically between Minnetonka and the city. Their project is to continue the Hennepin avenue line out West Lake street to St. Louis Park and thence in a direct line to the Hotel St. Louis at Lake Minnetonka, making the route little more than nine miles in length. Rail routes vary from twelve to eighteen miles to Minnetonka, and this shortening of distance would give the electric line a very great advantage in connection with the cheaper fares which it would of course be able to make. An electric line is emphatically what Lake Minnetonka and Minneapolis need for the immense summer travel that there is between them. The signal success of the interurban electric line is wha has led to the Minnetonka project. The gentlemen interested have no doubt that an electric line from Minneapolis to Lake Minnetonka would do a larger business than the interurban line, and the company which establishes such an enterprise will doubtless pay dividends the first year. Mr. Lowry was interviewed on the subject the other day, but declined to state anything definite with regard to it, confining himself to the general statement that the policy of the new street railway company would be against building new roads and extensions. This is well understood, but it does not prevent other corporations being formed to carry on the work.

The electric line between Minneapolis and Robbinsdale is completed, with the exception of a short distance on Thirty-second avenue, north, the construction of which is hindered by the attitude of the Minneapolis Street Railway company. There is about half a mile between the end of the Penn avenue line and the city limits, and under the terms of Mr. Lowry's franchise no one can build this track but himself. He holds off for reasons that are best known to himself. The matter is to be laid before the city council by residents of Robbinsdale as well as Minneapolis, and action requested in regard to the matter. It is probable that it will be satisfactorily adjusted, and the line in operation before winter.

Superintendent Sharp, of the Twin City Street Railway company, has resigned in order to accept a position with the New York Electrical Construction company. Mr. Heild, who has been acting as superintendent of electrical construction of the local lines, takes Mr. Sharp's place. J. T. Calderwood, formerly city auditor, has been appointed auditor of the Twin City Street Railway company, the place having been created recently.

Dr. C. H. Bates, a Minneapolis dentist, has perfected an electrical invention that is intended to do away with the overhead wire in electric street railways The invention is a closed conduit for the trolley wire laid on the ties between the rails. There is a slot-closing device consisting of three wheels, one of which on the passage of the car compresses downward the half inch strip of steel that is used for closing the slot. The other two wheels of the trolley meanwhile run in separate grooves upon a copper track, and keep up the current. Lead packing makes the conduit water tight. There is a lead cushion for the steel strip on the edge of the slot, but it is so arranged that [illegible] touch it. Dr. Bates [illegible] organizing a stock company for the introduction of the invention. It is said that the matter has been brought to the attention of Mr. Lowry with favorable [illegible]

Col. Clowry, vice-president of the Western Union Tele[illegible]

Milwaukee, Wis.

MILWAUKEE, Wis., July 18 —Matters electrical took up a great deal of the common council's last session. The mayor's veto of the Western Union extension resolution was sustained, and the judiciary committee's report in favor of the Western Union's aerial cable scheme was tabled. The ordinance extending the franchise of the Milwaukee Power & Lighting company was ordered to a third reading, but an effort to secure a final adoption under suspension of the rules was defeated.

Whether or not the wires of the Western Union Telegraph company strung along the streets of Milwaukee shall be forcibly removed depends upon the opinion of the city attorney, which was recently called for by the board of public works. An ordinance has been passed ordering the board to cut down the poles if not removed by June 1st. An extension was granted to July 1st, but the later ordinance did not contain the order for forcible removal, and the board is in doubt as to whether the whole of the first ordinance was killed by the superseding one.

The work of track laying on the Rapid Transit line running from the terminus of Walnut street to Wauwatosa has been commenced, and by September the road will be in operation. Electricity will be the motive power. There is talk of the company purchasing the Wauwatosa Electric light plant, and using it for power purposes. Storage batteries have been proposed, too, and then again it has been suggested that the necessary power be taken from the Pabst brewery. Capt. Pabst is interested in the road, and has just erected an immense power house at the brewery.

On the other Wauwatosa line, the Milwaukee & Wauwatosa railroad, work is also progressing. The stone foundations for the viaduct—2,100 feet long—across the Menomonee Valley are being laid. The construction of the viaduct is the principal work remaining uncompleted.

C.

Nashville, Tenn.

NASHVILLE, July 18.—The work on the various extensions of the present street railway system is steadily progressing. The United Electric company is extending its Line street line to the Clifton pike on the old Charlotte road. The most important extension is the Maplewood, and on this more than half the track has been laid.

At the annual meeting of the stockholders of the Overland dummy line the report of an expert appointed some time ago to estimate the cost of converting the line into an electric road was read, and is now under consideration. The directors have under advisement the extension of this line to Franklin, the county seat of Williamson county, and distant from this city 18 miles.

The project to convert the West Nashville dummy line into an electric road has been abandoned as impracticable for financial reasons and the company has also been denied the privilege of freight transportation because of the fear on the part of the citizens and the city government that the line would fall into the possession of the Louisville & Nashville Railroad company, which already enjoys a monopoly of ingress to the city. Now the dummy line company has made an official statement to the effect that this favor must be granted, or something else done to prevent the sale of the line by foreclosure, in which case the road would almost certainly be bought by the Louisville & Nashville. The situation was brought about by the fact that the public greatly prefers to travel on an electric road, and there is one running to the point reached by the steam dummy; therefore its passenger traffic is no longer profitable.

The shortage of Mrs. A. A. Alexander, ex-treasurer of the Cumberland Telephone company, has been made good. The alleged embezzlement extended over a period of seven months, and the plan said to have been adopted was very simple. As the amounts were abstracted they were charged up to the Memphis Telephone company, which is a branch of the Cumberland Telephone company, and the shortage appeared on the books against the Memphis branch. Mrs. Alexander still claims entire innocence. Hitherto she has always borne a most excellent character.

D. W. B.

Toledo, O.

TOLEDO, July 18.—The directors of the Toledo Electric company held a meeting recently to discuss plans for a new [illegible]

At present the quarters on St. Clair street are much too small. The company contemplates erecting two fine fireproof [illegible] one story in height, as soon as a suitable location can be secured.

[illegible] and L. B. Dodge were appointed a committee to [illegible] As the company desires railway [illegible] property adjoining the Wheeling [illegible] Lake Erie railroad, below Lagrange street, is spoken of as the probable site.

The jury in the great street railway damage case returned a verdict recently in favor of the "Robisons," by settling the price for the use of the tracks on Summit, Monroe and Ottawa streets, a distance of about ten blocks, at $12,333.40, and damages to the rest of the property at $3,308, thus ending the 110 day suit.

This total, $15,641.40, it will be seen, is less than was paid for Adams street from Michigan to Summit—$17,500—a distance of six blocks.

Samuel W. Allerton, the manager of the City Street railroad of Chicago, testified in this case, and said that the part of the Consolidated system which the Robisons desire to appropriate is worth $400,000. Mr. Lang, general manager, had placed it at $350,000. The attorneys for the Robisons objected to the court admitting such testimony, declaring it to be in violation of all previous rulings. Such a price, they said, would keep the plaintiff from the use of the tracks.

Besides Mr. Allerton, W. E. Hale, president of the Consolidated, Mr. Yerkes of the North and West Side cable roads of Chicago, and President Shaffer of Indianapolis testified.

Last Tuesday Judge Millard of the Probate Court refused to grant a new trial in the last and most important condemnation suits. Exceptions were noted, and the Robisons paid $17,310.69 in checks to the court, and the verdict was confirmed. Of this amount $15,641.40 is the amount awarded by the jury as compensation and damages, and $1,669.29 is the costs in the case. This money will not be accepted by the Consolidated, as it would be a surrender of the case and prevent the appeal which will be going on through the higher court. And Mr. Robison holds that even should the higher courts reverse the lower, it would never work a removal of the cars from the streets, but merely make a change in the amount fixed for compensation. Judge Millard begins his decision as follows:

"It lacks but three days of five months since the hearing of this case was begun in this court. Twenty-seven actual days of that time was taken by the jury which brought in the verdict now asked to be set aside.

"Under the first head of the notice for a new trial forty grounds are set forth as error, and three other subdivisions are given in the same motion, but in the nature of independent motions on nearly all of these the court has ruled in some form during the preliminary hearing on trial, and I yet see no good reason to change the rulings before made."

He named three reasons as most strenuously urged by the Consolidated. The first of these was that no proof of the fact that Toledo is a city of the third grade of the first-class had been made. He said that the Consolidated had elsewhere admitted this to be a fact, and pointed to legal decisions.

The second ground was that John Brown was summoned as a juror, and that Michael Brown answered to his name and sat as a juror. He answered all questions satisfactorily, and "to every appearance was a model juryman." His wife had taken the summons to Michael, with the assurance that it was for him, and he is sometimes called John Brown The judge did not think he was warranted in setting aside the verdict for this reason, after the trial had been finished, and no injury had resulted therefrom. The juror would have been set aside, however, if a challenge had been made. Brown, it is said, was instrumental in having the amount increased several thousand dollars.

The inadequacy of the verdict was the third point, and "it is one which will be left to go with the others." His honor believed in the capacity of the jury, and did not feel warranted in setting up his judgment against theirs.

The struggle between the two companies has been a long one, and the new company has been fought at every step by the more powerful corporation already in possession of the right of way, as it deems any additional franchises an infringement on its right.

Three years ago Mr. Robison promised the city council that he would run three or six routes of electric cars into the various suburbs of the city. This has been done, and to day there are five separate lines of cars in full operation. They have more than doubled their rolling stock; their engine force at the power house and the number of dynamos for the generating of electricity. They are also double-tracking their system with a 78-pound steel girder rail and extending their lines. They find this necessary to carry out their purpose of giving the city the best possible accommodations in rapid transit.

The Robisons have leased the building now occupied by J. W. Green & Co., pianos, corner Summit and Madison streets, where their general offices and transfer station will be located.

Judge Doyle, one of the attorneys for the Consolidated,

in speaking of the case said, 'Oh, no, it is not ended yet, it is just the beginning I will bring up the constitutionality of the law, for one thing, in the higher courts. And I don't and will not believe that the court will permit property that the Consolidated can sell any day for half a million to be given away for $15,000. It is the most atrocious robbery I have ever seen in this city."

Superintendent H. B. Wood of the Toledo Electric Street Railway company has severed his connection with the company to accept a position with the Put in-Bay Hotel and Steamboat company. Assistant Superintendent Whitton has been promoted to the position of superintendent.

The electric cars on the Consolidated are now running as far as Bellevue Park. The company has received ten new cars and two 250-horse power genera ors.

The Robisons have received six new motor cars from Lynn, Mass., and four new Westinghouse motor cars from Pittsburg. They are putting in place a new 500 horse power engine, which will be ready for use soon.

H. S. Walbridge is now getting the right of way for the Maumee electric street railway from Schuetzen Park into the city. F. C. H.

Indianapolis, Ind.

INDIANAPOLIS, Ind., July 18.—John P. Barrett of Chicago, chief of the Department of Electricity of the World's Fair, was in this city Wednesday visiting different manufacturers of electrical machinery in the interest of the great fair.

The Primier Steel company is about to add a new branch of manufacturing, having purchased the electrical and other patents for elevators of Frank Herdman, who has been connected with the Hale Elevator company of Chicago.

A company headed by President Kerper of the Cincinnati street car lines has secured all the options and rights of way of the old Broad Ripple Electric railway, and has been promised the right of way over several streets in the city. Electricity is to be used on all lines. M.

Concord, N. H.

CONCORD, July 18.—The Shawhan Electrical Works were incorporated on the 11th inst., with a capital of $50,000. The company will manufacture dynamos, motors and storage batteries for railroad use J. F. Shawhan, formerly of Detroit, Mich., will manage the new firm. Buildings have been secured, and work will be begun immediately.

The street railroad company here is opposed by an obstinate city council that objects to every proposed improvement or extension, notwithstanding the expressed wishes of the property owners. The superintendent, George W. Pierce, has labored hard and faithfully to bring the road up to its present efficiency. He has added more cars, a generator, engine and boiler, and the service of the road, as far as it extends, is all that could be desired. The route of the west end extension has been filed, and awaits the tardy routine of the council. C.

Louisville, Ky.

LOUISVILLE, Ky., July 18.—The new electric street railway on Market street was put in operation last Monday, and thus far has proved a great success. The line is about eight miles in length, extending across the city east and west. The cars are running now on a six minute schedule, but it is the intention of the company to run them every four minutes after August 1st. With the completion of this line Louisville now has forty-eight miles of electric street car service.

The Highland Street Railway company of New Albany, Ind., has contracted with the Edison company for a 100 horse power station equipment with which to operate its motors.

The Louisville Consolidated Street Car company has ordered of the Edison company a 1,000-horse power station equipment for its eastern power house.

W. F. Ferris of the Edison company of New York was in the city yesterday. He had just returned from Evansville, Ind., where he closed a large arc light contract with the city, and disposed of a mining plant to Ingle & Co., coal miners.

The Thumm Electric company has purchased of the Edison company a large dynamo and motor for experimental work.

The contract for wiring the Board of Trade building for 500 lights has been given to the Edison company.

The Balme Hotel company has contracted for an Edison 250 light machine.

The new factory of the Gaynor Electric company on Fifteenth street was completed Tuesday.

The Edison company has moved into its new quarters in the Louisville Power company's building on Third street near Green. They are much larger and more convenient than those which the company occupied before. The company now carries a full line of all styles of dynamos, motors, wire and fixtures. Before, owing to the crowded quarters, the company was able to handle only the smallest machinery. C. C. Y.

PERSONAL.

Alex. H. Lewis of Cincinnati was in Chicago last week and was heartily received by his old friends in the electrical fraternity.

F. N. Armour, who has been connected with the Chicago Edison company about two years, has resigned his position to assume the management of the isolated lighting department of the Northwestern Thomson-Houston Electric company at St. Paul.

Chas. A. Schieren sailed for Europe July 16th on the steamer "Fuerst Bismarck." Mr. Schieren will visit the International Electrical Exposition at Frankfort, where he will inspect the various devices for transmitting power by belting.

D B Dean, representing the Electric Merchandise company, Chicago, has just returned from a trip to the Pacific coast. Mr. Dean reports the outlook on the coast as extremely flattering, and says the electric railway business will experience a great boom in that territory the coming year.

O. B Osgood of the railway department of the Chicago office of the Westinghouse Electric & Manufacturing company has been appointed general manager of the Westinghouse railway department for the southeastern district, with headquarters at Atlanta, Ga. His territory comprises North and South Carolina, Georgia, Alabama, Florida, Louisiana and Tennessee; the last two named states being added to the district for the first time. D. A. Tompkins, the general district agent at Charlotte, will continue to manage the lighting department.

NEW INCORPORATIONS.

Artelectro company, Cleveland, O.; capital stock, $1,000,000; to manufacture and sell electrical devices of all kinds.

Columbian Electrical Works, Chicago; capital stock, $3,000,000; to manufacture, sell and use all classes of electrical apparatus.

Berkeley & Lorin Water & Light company, San Francisco, Cal.; capital stock, $250,000; to purchase, lease and sell water, water rights, light and power privileges and franchises.

Gaston Electric Manufacturing company, Sparta, Ill.; capital stock, $125,000; to manufacture, sell and apply any and all kinds of electrical and other machinery, apparatus, appliances or devices.

ELECTRIC LIGHTING.

The Napa, Cal., street lighting contract was recently awarded to the local Thomson-Houston company.

A number of Marion, Ind., aldermen were in Chicago last week to study the city's electric lighting system.

At the meeting of the board of directors of the Elgin Insane Asylum, July 16 h, the contract for installing a plant in the asylum was awarded to the National Electric company of Eau Claire, Wis.

Princeton, Ill., is proud of a new electric light plant, established by the Princeton Electric Light & Power company. The Thomson-Houston dynamo is used, and there are two dynamos, one having a capacity of 30 arc lights and the other capable of supplying 650 incandescent lamps.

The Western Electric company has just installed at Salem, Ind., for the Salem Electric and Artificial Ice company a 500 light National alternating dyanmo and a 50 light Western Electric arc plant to be used for both city and commercial lighting. The plant was put in under the supervision of W. H. Schott. E. Craycroft has been appointed superintendent. The plant is most complete in all its details.

The Oakland, Cal., Light & Motor company has decided to invest between $200,000 and $300,000 in extending its plant. New engines and boilers will be put into the Webster street building, and dynamos to furnish current to 100 additional arc lights and 3,000 incandescent lights will be installed. The incandescent lights will be on a meter system. New wires and poles will be put up and a power system will also be established.

The San Antonio Light & Power company has been formed in Los Angeles. One of the objects of the new incorporation is to utilize the waters of San Antonio creek in the counties of Los Angeles and San Bernardino for operating an electric light and power plant. The directors are Thomas R. Bard of Hueneme, N. W. Blanchard of Santa Paula, J. A. Dale of Pomona, John A. Hooker of Los Angeles, M. R. Campbell and C. G. Baldwin of Claremont, and A. W. Burt of Redlands. The capital stock has been placed at $240,000.

Carl Hoffman, Henry Ettenson, E. Michael, C. M. Salinger, Herman Bruns, J. H. E. Weigant and W. B. Walker have formed a company at Leavenworth, Kan., for electric lighting The capital stock of the company will be $50,000. A special meeting of the city council will be held to consider the granting of a franchise to the new company. At the last meeting of the council an ordinance was presented granting the franchise, but the matter was laid over on the ground that the company at that time had no existence, having never been incorporated.

[illegible] laboratory.

[illegible] Electric company for a plant consisting of one 10,000 and [illegible] lamps for its new building. Special permission was obtained for concealing the arc light wires in this building and a high grade of rubber covered wire will be used, [illegible] ing. A circle of six lights will be placed on the flag staff, so arranged that they can be [illegible] perfect ease by one man. Special fixtures for suspending the arc lamps, a number of which will be placed on the front of the building, have been designed, and the wires leading to these fixtures will be brought through the building front. In order to accomplish this, it will be necessary to drill in some cases through five feet of brick and terra cotta, and in other places through about three feet of solid granite.

ELECTRIC RAILWAYS.

The Boise City, Idaho, electric railway will soon be in operation.

An electric line is proposed at Auburn, Cal. The generators will probably be operated by water power.

The West Asheville, N. C., & Sulphur Springs Railway company has let the contract for an electric power plant to operate its street railway.

A syndicate headed by Commodore W. J. Kountz of Pittsburg will commence at once the construction of an electric line at Yankton, S. D.

Contract has been left for building the first mile section of the electric road at Alberquerque, N. M. The road must be completed within one year.

A franchise has been granted for an electric line between Redwood City, Cal., and Baden. Fifty thousand dollars' worth of work is to be done the first year.

It is said that Pittsburg capitalists have decided to convert the Paterson, N. J., street car lines into an electric system, and anticipate the change will cost $350,000.

The West Side Rapid Transit company of Salt Lake City contemplates replacing its steam dummies with the storage battery system, as there is considerable objection to the operation of the dummies within the city limits.

The Davenport, Iowa, Electric Railway company has petitioned the city council for permission to pipe the streets for the purpose of supplying steam for heating purposes in the business portion of the city, with the intention of extending it later into the residence district.

By the extensions now about completed the Cicero & Proviso Electric railway of Chicago has about eleven miles of double tracked road. The company will soon carry passengers from the western terminus of the Madison street cable line to the cemeteries along the Desplaines river.

The Santa Monica Wharf & Terminal Railway company of Los Angeles is considering the question of changing its line to connect with the electric system by way of the Pico street line, and operating the whole road by electricity. The company has nearly all the right of way, and good terminal facilities at Santa Monica have been secured. The plan includes a wharf and complete shipping facilities.

In the federal court of Indianapolis the Edison General Electric company last week filed suit against the Broad Ripple Rapid Transit company of that city. It is alleged in the bill that the Edison company contracted with the incorporators of the Transit company to build an electric line and delivered $40,000 worth of material. When the work had been let to the sub-contractors it was discovered that the Transit company was not responsible. The Edison company has been sued by all the sub-contractors and now demands a judgment of $100,000 in damages for the alleged deceit practiced by the Transit company.

ELECTRIC MINING.

An electric tramway, the first for this purpose in Canada, will be put in the new Vancouver coal mines at Nanaimo, B. C. The plant, of which the first installment will cost $20,000 consists of an [illegible] horse power generator and two 30 horse power electric locomotives, each of which will haul at a speed of nine miles an hour [illegible] cars. Other generators will be used to furnish lights in the mines, 600 of which will be used. Electricity will also be employed in working coal drills and cutters.

Dr. Kosmann and Messrs. Lange and Brieg, says the [illegible], have recently proposed a new electrolytic separation of zinc, capable of being applied on a large scale. The process consists in the simultaneous preparation of metallic zinc and [illegible] acid by electrolyzing solutions of the sulphite of zinc or other soluble salts of this metal in the presence of free sulphurous acid, the latter being [illegible] in the form of gas or as a liquid. The sulphurous acid, SO_2, is obtained on a large scale in the [illegible] of [illegible]. It is either kept in solution in water, or else used as such

as produced, being passed into the electrolytic bath. In the separation of zinc on a large scale by this process, the zinc bearing mineral is partly roasted in the presence of some form of carbon or even an organic debris. It is then crushed and well mixed with water, either in a vat or revolving drum. The powdered mineral is kept in suspension in the liquid by constant agitation, and at the same time sulphurous acid gas, arising from the roasting of other zinc ore, is passed in; the result is the formation of sulphite of zinc. The liquid is now exposed to electrolysis, either in the same vessel or after removal to a more convenient receptacle, and while electrolytic action is going on, sulphuric acid gas is still passed in, so that all the oxygen that is produced during electrolysis becomes used up in the formation of sulphuric acid.

TELEGRAPH.

Experiments made at McGill university demonstrate the fact that a telegraphic signal can be sent from Montreal to Ireland and back, a distance of 8,000 miles, in 1.05 seconds.

On July 17th, several assumpsit suits were filed against the Hyde Park District Telegraph Electric company, Chicago. William Kemp sued for $1,000; John W. Wheelock, $75; William Mueller & Co., $200, and George F. Ebert, $1,000.

The Postal Telegraph & Cable company has had a large force of men engaged for some time in laying a submarine cable from Oakland, Cal., to Goat Island, which, when completed, will be connected with one similar extending from the Clay street wharf in San Francisco to the west side of the island. The company's men have stretched the aerial cable from the company's office at Market and Post streets, across Market to the south side of the street. This cable will run to the Clay street wharf, where a connection will be made with the submarine cable, thus completing the circuit. The total length of the cable to be laid will be nearly eight miles, five of which will be submarine. It is expected that the cable will be in working order by the latter part of the month.

MISCELLANEOUS.

Eastern capitalists are reported as about to erect a plant in Middlesborough, Ky., for the manufacture of electrical devices.

An electric transfer table 70 feet long, and with a capacity of 225,000 pounds, is now in use in the Denver shops of the Union Pacific railroad.

The National Electric company has been incorporated at Alexandria, Va., with P. Mason, president, and W. J. Dante, secretary. The capital stock is $1,000,000.

Herbert Longfellow of Henrietta, N. Y., was killed by lightning last week while storing hay in a barn. Two men who were assisting Longfellow were prostrated by the shock, but will recover.

The United States Corporation Bureau of Chicago reports 245 completed corporations in the United States for the week ending July 17th, with a total capitalization of $121,470,350, including sixteen light, heat, power and transportation companies, capitalized at $12,870,000.

The Ohio state university at Columbus has an electrical engineering course among its departments. Two new buildings are to be erected the coming year. Three new departments have just been created, and two more professors in agriculture and botany are soon to be added, making the total number of teachers forty-five.

It is proposed to hold a large international electrical exhibition at Melbourne about the end of the present year. The exhibition will be held in the exhibition building used for the Centennial Exhibition of 1888. To obtain exhibits and support from those countries in which great attention is paid to electricity, the Victorian government has been approached, not with the idea of obtaining a subsidy, but merely for countenance and assistance in communicating

[illegible] has a story—apparently more ingenious than truthful—of the manner which a deaf man took to inform himself when his electric door bell was rung. In one of the rooms of his house he fastened an electro magnet on the wall about four feet from the floor. The armature [illegible] so that when it was attracted by the magnet a catch was released and a [illegible] was a section [illegible] two feet [illegible] made between the armature and the magnet the log dropped to the floor [illegible] could not hear [illegible] apprised him [illegible]

TRADE NEWS.

[illegible]

entitled "Magnolia Valse" by Caroline Bennett Knott. It is also indebted to this company for a fac-simile of a very handsome gold medal awarded it at the exposition held at Edinburgh last fall.

Milliken Bros., New York and Chicago, have lately completed tests made at Cornell University of their poles showing ultimate strength, elastic limit and corresponding deflection in connection with standard pipe and wooden poles. A complete report of the tests is promised at an early date.

After several years of severe tests the Law battery has attained a position which, for practical results, is second to none on the market. The Law Telephone company is receiving orders from foreign countries which are keeping it very busy, although this is supposed to be a quiet time of the year in the electrical trade.

BUSINESS.

Samuel T. Williams, 447 North street, Baltimore, reports that hardly a day passes that he does not receive new orders for his engine, which he sells under a guaranty of regulation within one per cent. It is said that some of these engines that have been in use over six years are today as good as new.

J. Lang & Co., 44 Michigan street, are building for the Edison company two large switches, to be used in the Auditorium. These switches are of the Andress double pole pattern, one of 1,600 amperes and one of 1,000 amperes. They are to be mounted on mahogany bases, highly polished, and of thoroughly first-class workmanship throughout.

Brownlee & Co. of Detroit have just designed and built a large lathe to be used in turning a round pole to be used for street railway and electric light work which they are offering at a price but a little above that asked for the ordinary cedar pole. These poles are symmetrical, the lathe making a uniform taper, and when painted will undoubtedly make a very handsome and serviceable line.

O. A. Foster, 8 Oliver street, Boston, has just sent out to the trade a handsome little catalogue illustrating and describing his 1891 electric motor and 1891 electric battery. For the motor, simplicity, economy, durability and low price are the great advantages claimed; and for the primary battery, that it is the most efficient and economical yet brought out. The catalogue is gotten up in an attractive style.

The Johnson Electric Service company, 113 Clyburn street, Milwaukee, is having an unusually busy season thus far and reports the outlook as most promising for the coming fall and winter. The owners of fine buildings are coming to appreciate the convenience of the heat regulating device built by this company, and are also coming to understand the saving that results from its use. In a large building by keeping a uniform heat the saving in one season, it is claimed, will amount to nearly the entire cost of the appliance.

Milliken Bros. of New York and Chicago still report business rushing. In the line of iron roof work, of which this firm makes a specialty, they have lately secured contracts for Allentown, for the new electric line, for a large boiler house at New Orleans, La., and for the Newark, N. J., power house. After sharp competition they have secured contracts for their patent poles for the new electric line in New York city and at Providence, R. I. Both contracts are large. At the suggestion of Mr. McIntire this firm has introduced a new form of eye bolt in tops of poles which contains an additional insulator. It is made in the form of a fork having a special porcelain insulator in the end.

Geo. H. Bliss and F. H. Soden, both well known to the business and electric interests of Chicago, have formed a co partnership under the name of Bliss & Soden to conduct business as electrical experts, engineers and contractors. Both gentlemen are pioneers in electric lighting in the West. Mr. Bliss opened the initial office in Chicago for the Isolated Edison company some years ago, and later was general manager of the Western Edison company, while Mr Soden during the last five years has been manager of the engineering and construction departments of the Western office of the Thomson-Houston company. These gentlemen are both competent, and will undertake nothing but high grade work. They will undoubtedly meet with the success they so well deserve.

The Columbia Electric company of St. Paul has just issued an attractive catalogue showing a large line of new apparatus that has recently been perfected and now for the first time put on the market. The Columbia company will manufacture motors from 1 to 50 horse power; power generators from 25 to 100 horse power, and dynamos from 25 16 candle power lamps to 500 16 candle power lamps capacity, and in addition a large line of specialities. The corporation is a strong one, having an extensive factory at Upton Grove, a suburban town, and a fine office and salesroom at 207 E. Fourth street. The officers are Egbert G. Handy, president; Jos. A. Humphreys, secretary and treasurer, F. S. Kirkpatrick, attorney, and Frank Mulligan, superintendent and electrician.

ELECTRICAL PATENTS.

Issued July 14, 1891.

[illegible] Lamp-switch. William M. Goodridge, Highland Park, Ill.

[illegible] especially designed for use as a part of the [illegible] apparatus of a telephone exchange.

[illegible] and Connection for Electric Railways. William Osner, Chicago, Ill.

[illegible] a contact bar or plate in connection with the [illegible] forming a slot for the passage of the shank of a current transferring arm. This current transferring arm has a contact wheel attached thereto, adapted to move in contact with the supply conductor.

455,765. Electric Motor. Harry H. Porter, New York, N. Y.

455,773. Alternating Current Motor. William Stanley, Jr., Pittsfield, Mass., and John F. Kelly, New York, N. Y.

The invention is based on the well-known property or feature possessed by a condenser of neutralizing or counteracting the effects of self-induction of a circuit with which it may be connected. It consists in the combination of a motor with a condenser included in the field circuit or that circuit having the higher self-induction.

455,788. Thermostat. Henry A. Chase, Boston, Mass.

455,789. Process of Manufacturing Insulated Conductors. Charles Cuttriss, New York, N. Y.

455,790. Dynamo-electric Machine or Motor. Justus B. Entz, New York, N. Y.

455,796. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa.

455,798. Trolley for Electric Cars. Walter H. Knight, Newton, Mass.

455,800. Electric Cut-off Apparatus. Edwin W. Rice, Jr., Lynn, Mass.

455,808. Electric Magnetic Ore Separator. Jonas Wenstrom, Orebro, Sweden.

455,809. Magnetic Separator. Jonas Wenstrom, Orebro, Sweden.

455,812. Fire Alarm Apparatus. Henry A. Chase, Stoneham, and Howard F. Eaton, Cambridge, Mass.

455,813. Thermostat. Henry A. Chase, Boston, and Howard F. Eaton, Cambridge, Mass.

455,815. Electro Phonometer and Phonoscope. Isaiah H. Farnham, Wellesley, Mass.

The invention consists mainly of a diaphragm mounted in front of and close to a magnet, and a coil or helix of insulated wire adapted by means of suitable connections to be included in any electric circuit, and capable of being moved along the magnet from end to end. Suitable means are provided for said sliding motion of the coil. An index or scale with pointer attached to the coil denotes the advance thereof on said magnet.

455,837. Electric Switch. Carl G. Dahlgren and John H. Svensson, Gothenburg, Sweden.

455,855. Electric Indicator. Earl C. Eldredge, Springfield, Mass.

455,856. Holder for Carbon Brushes of Commutators. Clarence H. Farrington, Milford, Mass.

455,873. Signaling Apparatus. Howard F. Eaton, Quincy, Mass.

455,887. Armature for Dynamo-electric Machines. Edwin W. Rice, Jr., Lynn, Mass.

455,898. Electric Motor or Dynamo-electric Machine. Charles G. Curtis, New York, N. Y.

In this invention each field magnet coil is surrounded by an independant water tight casing.

455,904. Insulated Electrical Conductor. Edwin D. McCracken, Alpine, N. J.

455,955. Lightning Arrester. Charles S. Van Nuis, New Brunswick, N. J., and Jonathan H. Vail, New York, N. Y.

455,956. Electric Railway System. Samuel P. Wilcox, Elkhart, Ind., and Joseph D. Partello, Rochester, Mich.

455,968. Secondary Battery Plate. John R. McLaughlan, Philadelphia, Pa.

455,971. Armature for Dynamos. Frederick L. McGahan, Indianapolis, Ind.

455,972. Electro Medical Lighting Apparatus. Paul Oudin and Henri O. Kratz-Boussac, Paris, France.

455,981. Apparatus for Administering Electricity. Geo. H. Bethel, Sydney, New South Wales.

455,984. Magnetic Separator. Henry G. Fiske, New York, N. Y.

455,985. Magnetic Ore Separator. Henry G. Fiske, New York, N. Y.

455,986. Terminal for Electric Batteries. Hammond V. Hayes, Cambridge, Mass., and Angus S. Hibbard, Morristown, N. J.

We quote claim two:

"The combination of a voltaic battery and terminal attachments therefor, each consisting of a copper wire molded to its respective battery-plate and each adapted to form a soldered connection with its complementary circuit wire by a coating of solder or easily fusible alloy applied to its free end."

156,066. Street or Station Indicator. William T. Snedden, San Francisco, Cal.

156,021. Electric Belt. Lewis N. Fancher, Kansas City, Mo.

156,023. Railway Time Signal. Joshua C. Dickover and Walter Scott, Hot Springs, S. D.

156,098. Street or Station Indicator for Cars. Geo. H. Tietjen, San Francisco, Cal.

156,110. Automatic Circuit Closer for Telegraph Keys. James W. Brown, Van Wert, Ohio.

156,120. Insulated Electric Conductor. Edwin D. McCracken, Alpine, N. J.

The conductor is surrounded by insulating cords ranged practically parallel and is in contact with them, but the insulating cords are separated from each other. An exterior insulating material holds these cords in place.

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and **is guaranteed to be waterproof, and will not deteriorate, oxidize or crack,** and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

HIGH GRADE INSULATED WIRES

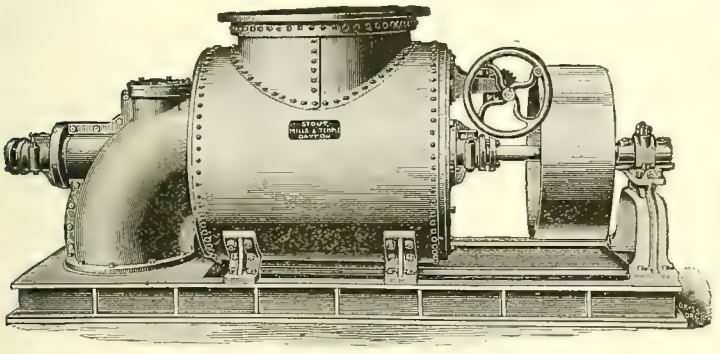
OF ALL DESCRIPTIONS.

WEATHERPROOF WIRES,
OFFICE AND ANNUNCIATOR WIRES,
MAGNET WIRES,
INCANDESCENT LAMP CORDS,
ETC., ETC., ETC.

Our facilities are such that we are prepared to fill orders of any size.

WRITE FOR QUOTATIONS AND SAMPLES. | **CHICAGO INSULATED WIRE CO., 48-52 N. Clinton St., CHICAGO, ILL.**

The New American Turbine Water Wheel.



PARTICULARLY ADAPTED TO DRIVING

ELECTRIC LIGHT AND POWER STATIONS,

On account of its high efficiency at all stages of gate, steadiness of motion and easy working gate, the construction of which makes it the most sensitive to the action of a governor of any wheel on the market.

SEND FOR CATALOGUE Illustrating various styles of setting on both vertical and horizontal shaft.

DOUBLE CARBON LAMPS

Afford the Only Reliable and Efficient Means for

ALL NIGHT ELECTRIC LIGHTING.

All other devices are crude, expensive and unsatisfactory.

THE BRUSH ELECTRIC COMPANY

Has established its broad foundation patent for Double Carbon Arc Lamps, No. 219,208, having ***won four distinct infringement suits*** in the United States Courts, two of them on final hearing, the decisions being rendered by Judges Gresham, Blodgett, Brown and Ricks.

The public is warned against the use of infringing lamps or any crude substitute for the Brush Invention.

Arc Lighting Apparatus,
Alternating Current Apparatus,
Electric Motors and Generators,
Incandescent Lighting Machines,
Carbons for Arc Lighting, Etc., Etc., Etc.

IMPORTANT TO BUYERS!

FOR SALE.—The Entire Stock of

ELECTRICAL SUPPLIES

OF THE

EMPIRE CITY ELECTRIC COMPANY,

15 and 17 Dey Street, - NEW YORK.

The directors of the Empire City Electric Company have deemed it best for the interest of all concerned to voluntarily dissolve the company and liquidate its affairs, and the Supreme Court of the State of New York has appointed me receiver. It being desirable to close up the business without delay, I offer for sale, in lots as wanted, the entire stock of General Electrical Supplies, consisting of:

HOUSE FURNISHING GOODS.

Electric and Magnetic Bells, Gongs, Electro-Mechanical Gongs, Batteries, open and closed circuits, of every description, Annunciators, Burglar Alarms, Automatic Drops, Wood and Metal Push Buttons and Gas Keys, large variety, Letter Boxes, Door Pulls, Door Openers, Binding Posts and Connectors, Gas Lighting Apparatus of every kind, Induction Spark Coils, Window and Door Springs, Window Tubes, Speaking Tube Material of all kinds, Fan Motors and Outfits, Gas Igniters, Porous Cups, Soldering Salts, Cleats, Rubber Tubes and Rods, Soft Rubber Tubing, Carbon Plates, Double-pointed Tacks, Staple Drivers, Sal Ammoniac, Blue Vitriol, Bichromate of Potash, Sulphate of Zinc, Quicksilver, Etc., Etc., Etc.

TELEPHONE AND TELEGRAPH GOODS.

Poles, Cross Arms, Oak and Locust Pins, Brackets, Glass and Porcelain Insulators, Cross Arm Braces, Lag Screws, Pole Steps, Nails, Spikes, Shovels, Spoons, Digging and Tamping Bars, Pikes, Soldering Stoves, Strip and Bar Solder, Screw Drivers, Vises, Eccentric Clamps, Tree Trimmers, Pliers, Pole Counters, Construction Tools of every Description, Telegraph Instruments, Binding Posts, Magneto and Extension Bells, Batteries and Battery Material, Zincs, Coppers, Blue Vitriol, Sal Ammoniac, Telephone Cords, Lightning Arresters, Torches, Blasting Apparatus, District Call Boxes, Splicing Clamps, Come Alongs, Hill's and Weldon's Climbers, Take Up Reels, Etc., Etc., Etc.

ELECTRIC LIGHT AND POWER GOODS.

Incandescent Lamps, Globes, Reflectors, Shades and Shade Holders, Wire Guards and Handles, Sockets, Cut-Outs, Main and Branch Blocks, Rosettes, Fuse Boxes, Fuse Links, Fuse Wire, Gas Attachments, Arc and Incandescent Switches, Flexible Cord, Glass Floor Insulators, Tree Insulators, Soldering Torches and Charcoal Furnaces, Electric Light Carbons, Testing Instruments, Tapes, Splicing Compound, Adjusting Balls and Cleats, Moulding, Cleats, Tool and Carbon Bags, Linemen's Body Belts, Splicing Clamps, Swing Ball Lightning Arresters, Vulcanized Fibre, Hard Rubber Sheets, Etc., Etc.

BARE AND INSULATED WIRES.

Hard and Soft Drawn Copper, Iron and Steel, German Silver and Fuse Wires, Annunciator, Burglar Alarm. Office, Magnet, Gas Fixture, Underwriters', Weather-proof and Rubber Covered Wires, Reels, Spools, Etc., Etc.

ELECTRO-MEDICAL APPARATUS

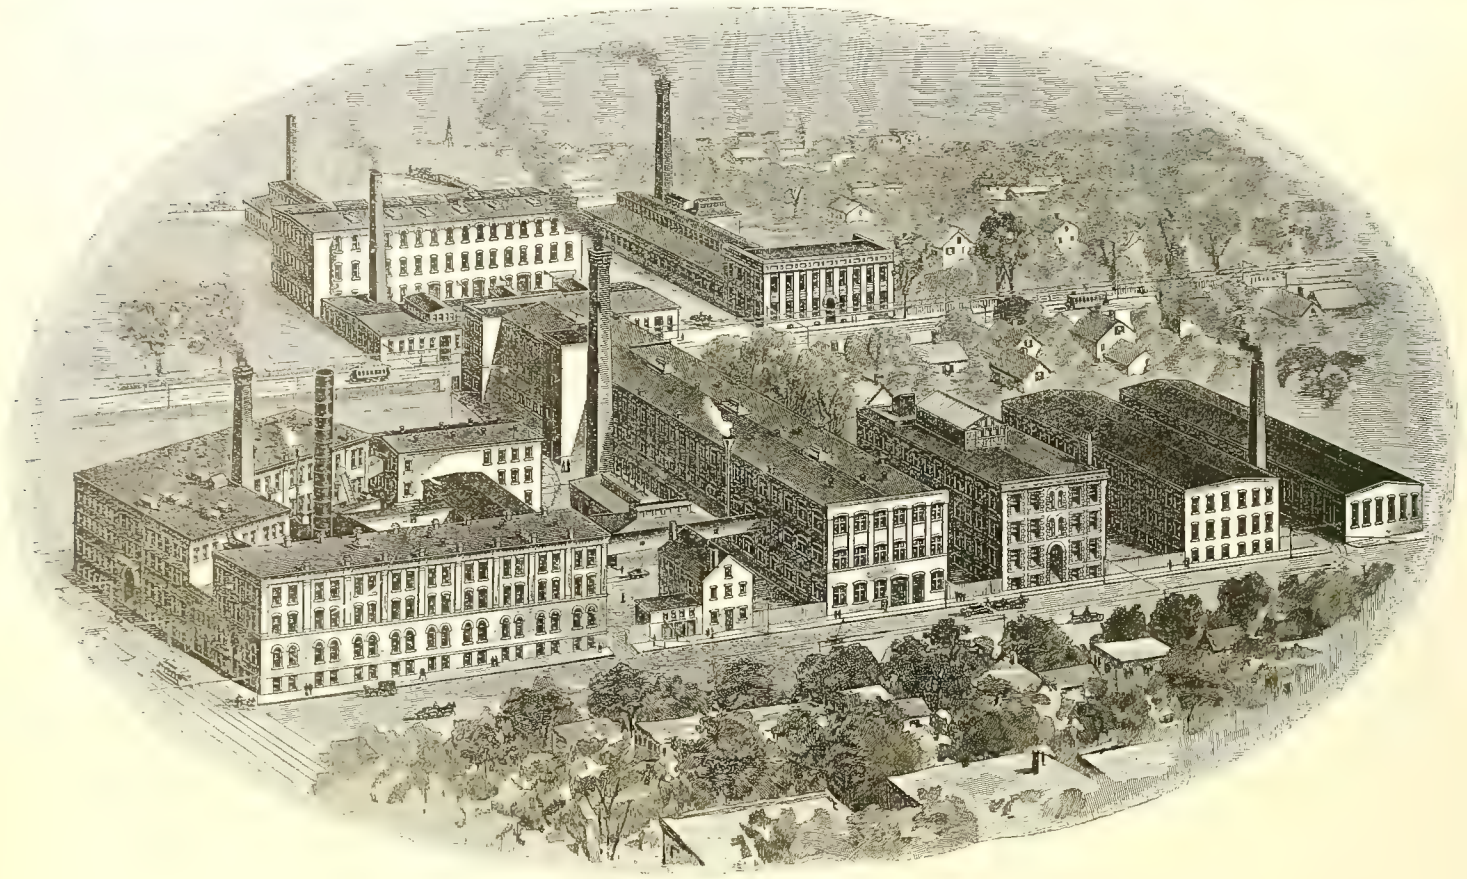
Of every description, including Empire, Perfection, Vesta, Florence, Williams, Kidder, Drescher, Gaiffe and other makes of Medical Batteries and Magneto-Electric Machines, Induction Coils, Handles, Cords, Sponges, Extra Zincs, Etc., Etc., Etc.

ALL IN FIRST-CLASS CONDITION.

Write for what you want if you cannot call and examine the goods.

CHARLES S. BEARDSLEY, Receiver, 15 & 17 Dey St., NEW YORK.

THE PROBLEM SOLVED.



CUT OF FACTORY, 1890.

TOTAL NUMBER OF LOCAL COMPANIES, JANUARY 1, 1891, USING

ARC APPARATUS.	DIRECT INCANDESCENT.	ALTERNATING.
630 Companies,	108 Companies,	415 Companies,
87,131 Lamps.	**79,905 Lamps.**	**435,550 Lamps.**

The above increase would seem to answer most emphatically in the affirmative.

All purchasers of Electrical Apparatus should thoroughly investigate the acknowledged merits of OURS before buying any of the CHEAP SYSTEMS now on the market.

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, unequaled for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Vol. IX. CHICAGO, AUGUST 1, 1891. No. 5

Henry M. Byllesby.

That an intimate knowledge of the scientific and mechanical branches is of great value to the head of an electrical enterprise is shown by instances in which experts have become successful managers. True, it is necessary in such cases to combine executive ability and scientific knowledge—a combination that is generally considered out of the question. Yet that there are such cases is known to all acquainted with the managers of the great electrical houses of this country. One of the most conspicuous of this class is Henry M. Byllesby, the subject of this sketch, whose portrait is herewith presented.

Mr. Byllesby was born in January, 1859, in Pittsburg, Pa., his father being the late Rev. D. C. Byllesby of the Episcopal church. His early days were passed at Mount Holly N. J. Later he accompanied his father to Allentown, Pa., and while residing there entered the class of 1878 at Lehigh University, Bethlehem. He was not able to complete his scientific studies at that institution, however, as he found it necessary to accompany his father to Roselle. While at Roselle he was for a time employed in the general office of the Central Railroad of New Jersey in New York city. From 1879 to 1882 he was employed by Robert Wetherill & Co. of Chester, Pa., as a draftsman and mechanical engineer.

In 1882 he became connected with the Edison company, and maintained this connection until 1885, spending most of his time as manager of the Canadian department of that company. In 1885 he accepted an offer from Geo. Westinghouse, Jr., to become eastern sales agent of the Westinghouse Electric company. Soon after he was appointed general manager, and then elected first vice president, holding these positions until December, 1890, when his resignation was reluctantly accepted. In February, 1891, he became connected with the Thomson-Houston Electric company. In May, 1891, he was elected vice-president of the Northwest Thomson Houston Electric company, with headquarters at St. Paul, and in June was promoted to the presidency of that company.

From childhood Mr. Byllesby has been interested in all branches of mechanics, his greatest pleasure as a boy being the building of miniature steam engines and other mechanical toys. He has always been an enthusiastic worker at his profession, and the patent office records bear evidence of the results of his work. His greatest success was, however, in directing and managing the mechanical and selling departments of the Westinghouse Electric company. Mr. Byllesby is a member of the American Society of Civil Engineers, American Society of Mechanical Engineers and the American Institute of Electrical Engineers.

HENRY M. BYLLESBY.

In 1882 he married a daughter of H. P. Baldwin, general passenger agent of the Central Railroad of New Jersey.

Mr. Byllesby is a man of fine physique, splendid business judgment, rare tact and has already made hosts of friends in St. Paul. The Northwest Thomson Houston Electric company is to be congratulated on its good fortune in having Mr. Byllesby at its head.

Electric Light Plant for the Masonic Temple, Chicago.

The contract for the electric light plant for the Masonic Temple in Chicago, which will be one of the largest isolated plants in the world, has been awarded to the western isolated lighting department of the Thomson-Houston Electric company. The generating plant will consist of six 80,000 watt generators, and between 7,000 and 8,000 ghts will be wired. Nearly every company in the field made proposals for this contract, and the isolated lighting department of the Thomson-Houston company naturally feels elated at securing it. In addition to the generating plant and wiring, an order was secured for about eight thousand Thomson-Houston incandescent lamps and the necessary sockets.

The New Ticket Distributer at the Chicago Telephone Exchange.

Some months ago the WESTERN ELECTRICIAN contained an article describing the manner of handling a "busy" call by an improved system which had been newly introduced in the main telephone exchange of the Chicago Telephone company. Within the last month there has been introduced an improvement which still further facilitates the handling of these calls. This improvement is a ticket distributer contrived and arranged by J. J. O'Connell, the company's electrician. Under the former arrangement the "busy" tickets were made out and distributed at the "target" or "busy" board, the call sometimes passing through the hands of several operators. With the aid of this new device the tickets are distributed to six operators, each operator receiving only the tickets belonging to her section. The distributer consists of a brass box, two inches in width and twenty one feet in length, having six channels, each channel terminating in a slot placed before an operator. Under the box passes a cotton band, forming an endless belt. At one end of the distributer is placed a desk composed of six sections, each section being provided with six slots, and each slot leading to one of the six channels of the distributer. At each section of this desk an operator is stationed, who receives the "busy" call, writes out the ticket and deposits it in the channel which bears it to the

operator at the [illegible] connection [illegible] nection.

Electricity at "A Night in Pekin."

On Tuesday, Thursday and Saturday nights of each week crowds of people fill the large amphitheater at the corner of Sixtieth street and Cottage Grove avenue, Chicago, where the big spectacular entertainment "A Night in Pekin" is presented. Behind the realistic bombardment of the city, its subsequent overthrow and the beautiful pyrotechnic display following, which are alone apparent to the eyes of the spectators, there lies the usual mass of detail and discipline necessary to accomplish these outward results. A representative of the WESTERN ELECTRICIAN, through the courtesy of Mr. [illegible] performance, was allowed to inspect the region behind the scenes. Among other interesting features is that of igniting the explosives by electricity. The equipment is somewhat similar to that used in blasting and mining operations. Four cells of battery furnish the necessary current.

The detonator, instead of inclosing the wire in a brass or a glass tube, as is usually the case, has its wire protected in a paper sheath. The platinum wire which is made especially for the current is delicate and thin. The fulminate caps attached to the wire are about ¾ of an inch in length. Separate wires are strung to each district of the city of Pekin which is destined to destruction. When the proper moment arrives, the electrician, by manipulating a switch and lever, turns the electric current on the different wires in rapid succession; the walls of the city tremble, the tall buildings totter, crash follows crash. Pekin has fallen.

J. Smith of Compton, N. J., is the electrician who plans and furnishes the electrical equipment for numerous spectacular shows which James A. Pain & Sons are operating in American cities. It will be remembered that Mr. Smith is the gentleman who managed and accomplished the blowing up of [illegible] in New York harbor some time ago.

Electricity at the World's Fair.

The foundations for the World's Fair electricity building have been put in and work will soon be begun on the superstructure.

Electric fireworks on an elaborate scale are proposed as a feature of the dedicatory ceremonies of the week of Oct[illegible] Eugene & Paul Champenois of [illegible] France, has presented a plan for a display that would be very imposing and attractive. One of the leading pieces is [illegible]

"The City of Chicago, personified as a statue of fire, seated, and surrounded by figures of the states of the American Union. She will receive the great powers of the world, which will defile one by one before the assemblage of states. As each figure passes [illegible] it will halt, bow, and then lay down its flag or shield at Chicago's feet and receive a [illegible] then pass on, disappear, and another take its place. This superb picture of itself will be a grand firework, for every point [illegible] which it is composed [illegible] or colored, and the successive appearance of the allegorical figures will be in multi-colored moving fire, making a marvelous and splended kaleidoscope, forming one part of the display. Innumerable pieces of fireworks will form the background of this [illegible] a surface of 24,000 [illegible] time for the display of the allegorical pieces can be from 30 to 40 minutes, and [illegible] time every night. At each [illegible] be changed, for it would be impossible to show the 40,000 or 50,000 effects comprised in [illegible] the space of half an hour. [illegible] display can be shown at no other [illegible]

stalled, than that of operating the electrical plant. About 2,800 horse power working for one hour, would be required. The display of rockets is accompanied by detonations more or less violent as is desired, or these can be entirely suppressed if unpleasant to the ear, in which case they can be replaced by one or more bursts of military music, which will make of the combined harmony of sound and fire a wonderful delight. The fireworks contain neither gunpowder nor dangerous explosives. In firing rockets there are none of the inconveniences occasioned by rocket sticks falling among the spectators, nor by sparks causing fires among neigboring buildings. Wherever the point may be that a "sun" or a star may suddenly appear, on the fleeting and capricious line of the rocket, the operator is absolutely master of the situation, making the display appear or disappear, as he may wish. The fireworks, whether fixed or moving, are as varied in effect as they are unexpected and harmless, even to spectators not six feet from them. Their duration is indefinite. There is nothing which can stop them, except the breaking of the electric current or the will of the electrician in charge. It is claimed that that which can be produced has as much diversity for the eye as has music for the ear, and the owners claim that they will sustain the artistic comparisons they make."

Train Lighting by Electricity.

An English system of train lighting by electricity was described in the WESTERN ELECTRICIAN of June 6th, and a special type of dynamo designed for this work by J. H. Holmes was illustrated. Further details of this system are now presented, the accompanying drawings being reproduced from the London *Engineering Review*. Mr. Holmes' system is an adaptation of the plan of driving the dynamo from the car axle. This system is generally condemned on account of the varying speed of the axle and the stopping and reversal of the train. Mr. Holmes claims, however, to have provided against all such emergencies and objections.

At the maximum speed of the train the magnets of the generating dynamo are excited by a high resistance shunt; when the speed becomes lower, an extra excitation is given to the magnets by means of secondary batteries and a small regulating dynamo in order to make up for the reduction of speed, and so keep the electromotive force at the terminals the same as before; and when the speed of the train becomes less than a certain minimum, or when it is stopping, a governor switches the generating dynamo out of the circuit, and the circuit is then fed temporarily by the accumulators until the speed rises again.

An elevation of the dynamo is shown in Fig. 1. By referring to this cut it will be seen that there are two dynamos, Q and R, whose armatures, A and B, are fixed to the same shaft. Q is the main dynamo for supplying current to the lamp circuit e, Fig. 2, and R is a smaller dynamo for regulating the main dynamo. The current from Q passes along the wires d to the main circuit e. The accumulators C are placed in a shunt from the main circuit The field magnets of the main dynamo have two windings, one a high resistance shunt a, and the other a low resistance shunt b. The shunt b is in series with the conductor of the armature B of the regulating dynamo R. Another shunt c magnetizes

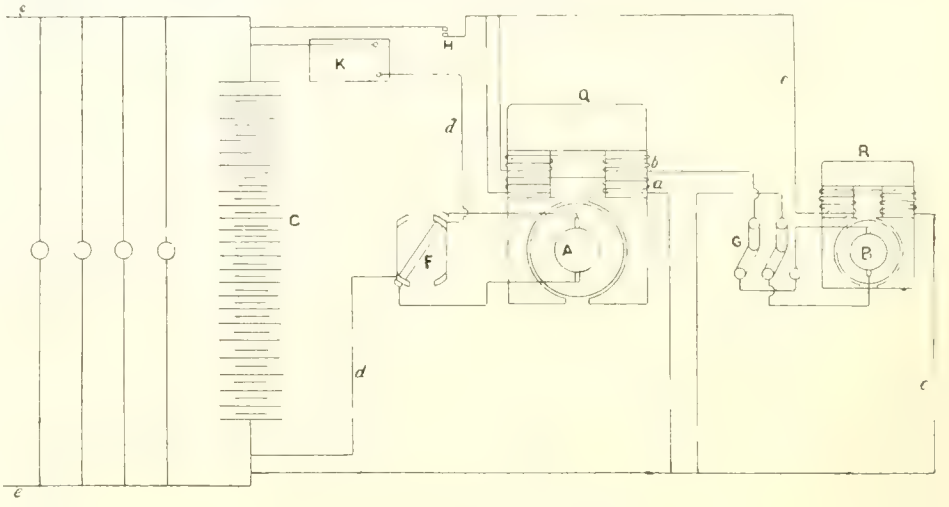

FIG. 2. TRAIN LIGHTING BY ELECTRICITY.

exited by the current in the high resistance shunt a, for the two currents in b neutralize each other. As the speed decreases so does the electromotive force in the armatures of the main and regulating dynamos. The currents due to the shunts a, b and c from the main circuits are practically constant for all speeds, owing to the presence of the accumulators C in the shunt. The magnetization due to a and c are therefore constant. The electromotive force in b due to the shunt is also constant, but the opposing

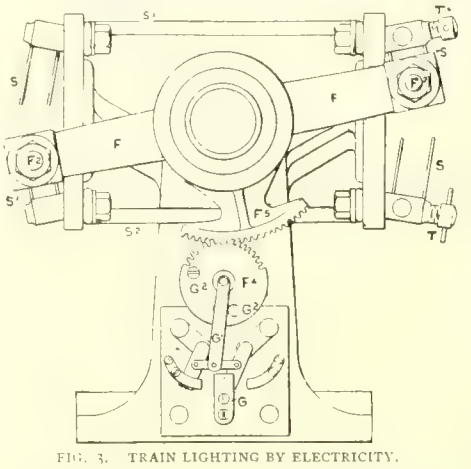

FIG. 3. TRAIN LIGHTING BY ELECTRICITY.

electromotive force in series with it, due to the armature B, becomes less as the speed decreases. The difference between these pressures supplies the field magnets of Q with extra excitation, and thus the electromotive force of the current generated in the armature A is raised again by an amount equal to what it lost by the reduction in speed of the train. When the speed of the train gets below a certain minimum, the governor M breaks contact at the switches H and K and puts the generator out of circuit with the lamps, the current of the accumulator then feeds the circuit until the speed of the train again exceeds the minimum speed. It will be seen therefore that the pressure in the lamp circuit is kept constant under all conditions.

There is a special apparatus which is an essential feature in the design of this dynamo, *i. e.*, for altering the lead and reversing the polarity of the brushes of Q automatically when the axle commences to revolve in the opposite direction, so that the current shall always go in the same direction along d, and also for keeping the direction of the current coming from the armature of R always in the same direction in which ever direction the armature revolves. The brushes D are radial to the commutator and are held in spring-holders D^1 which are carried by bars F^1 projecting from the movable arms FF. These arms F are mounted loosely on the armature shaft, and they can be rocked automatically from one position to another according to the direction of revolution of the shaft. The arms F are connected together by pins F^2. These pins are made to enter between one or the other pair of contact jaws S or S^1, which are connected respectively to the screw terminals TT^1 for the circuit wires, so that as the polarity of the brushes is reversed on the reversal of the direction of rotation of the shaft, their connection with the circuit is at the same time reversed by the movement of the arms F. The jaws SS^1 on the right hand side are coupled respectively with the jaws SS^1 on the left hand side by means of the copper bars S^2. A friction disk N is loose on the shaft and it carries a pinion N^1, which gears with a toothed sector F^3. This sector is fixed to a spindle which passes through the standard V and which carries at its other end a pinion F^4 gearing with a toothed sector F^5 on the boss of the arms F. A second friction disk N^3 is carried round by the shaft, but can slide longitudinally on it. This disk has a neck into which the ends of the governor M take. When the shaft is revolving very slowly and near its point of changing from one direction of revolution to another, the springs of the governor cause the arms to press the disk N^3 against the disk N and to carry it around by frictional contact. When this disk N is turned around with the shaft, it turns the pinion N^1, sector F and pinion F^4; the arms F are thus brought into the opposite inclined position, and the brushes moved to the right position of lead for the reversed direction of rotation of the shaft. As soon as the arms F have passed as far as they can into the jaws S or S^1, the disk N^3 will slip upon N. A groove in the disk N^3 is embraced by the fork of an arm N^4 which, when the disk is slid backward by the governor to a certain position, acts upon the pivoted arms H of two contacts and so cuts off the current from the shunts a, b and c. The spindle which carries the sector F^3 and the pinion F^4 also carries loose upon it an arm G^1, which acts upon a switch G so as to reverse the connection of the armature B with the circuit b, at the same time that the polarity of the brushes D is reversed; the motion of the arm G^1 is effected by pins G^2 on the pinion F^4. Fig. 3 illustrates the automatic brush shifter already referred to.

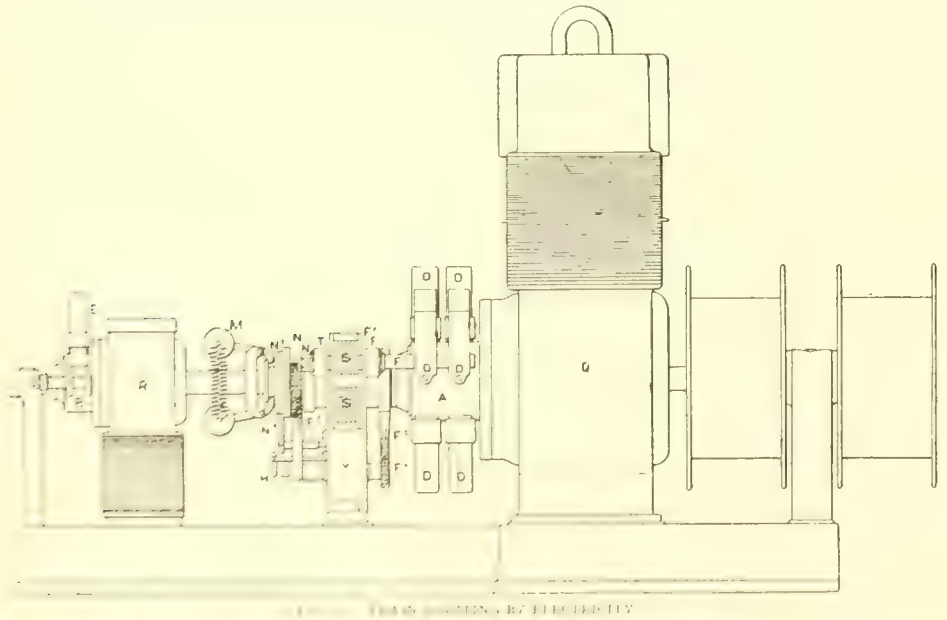

FIG. 1. TRAIN LIGHTING BY ELECTRICITY.

A movement is on foot to build an electric road from Port Norfolk, Va., to Portsmouth.

In a list of private soldiers of the regular army who have distinguished themselves by meritorious services *Harper's Weekly* mentions Private Gustave Kipper of the artillery. He showed that he was a good theoretical and practical electrician. He devised and set up an electrical apparatus for the artillery school, and invented a circuit-breaker for use in ballistic firing, and it did the work capitally, and so Kipper is mentioned, as he deserved, for specially meritorious acts or conduct in service.

Stations of the Edison Electric Illuminating Company at Paterson, N. J.

Until about a year ago there were two electric light companies in Paterson, N. J., and competition was rife. To-day a different state of affairs exists, and the Edison Electric Illuminating company has the field. The old Paterson Electric Light company, with its franchises and contracts, is now under the local Edison company's management. Prior to the consolidation the Paterson company was operating the Thomson-Houston arc and incandescent systems. The conductors were all overhead, and for incandescent house lighting the three-wire system was employed. Alternating current, however, was used for street lighting, and about 800 20 candle power incandescent lamps were in service. At that time the station equipment of the Paterson company consisted of eight one hundred horse power horizontal tubular boilers made by Smith of Paterson, N. J.; one 200 horse power Harris-Corliss engine; eight Ball engines of 90 horse power each; ten 400 light Thomson Houston incandescent dynamos; eight 50 light Thomson-Houston arc dynamos; and one 1,300 light alternator for the street lighting. The station supplied about 3,000 incandescent lamps and 290 arc lamps on city and commercial circuits.

The Edison plant, which, at the time referred to, was under the control of those now operating the united systems, consisted of two Babcock & Wilcox boilers of 300 horse power each; three Ball engines of 180 horse power each; one Ball engine of 100 horse power; one Buckeye engine of 175 horse power; eight 800 light Edison dynamos, and two 50 light Sperry arc machines.

The last mentioned company's system covered the business section of the city. The Edison underground tubing and a system of conduits for commercial arc lighting were employed. Both arc and incandescent systems are connected with overhead conductors in certain outlying districts.

About 5,000 incandescents, 55 commercial arc lamps and 80 horse power of motors took current from this plant.

Since the consolidation of the two interests many changes have been effected and others are in process. The entire commercial incandescent system, carrying 135 horse power [illegible] Edison station [illegible] of the two plants [illegible] Paterson company's station were withdrawn from service.

The reader can obtain a good idea of the completeness of the Edison plant [illegible] are respectively views of the dynamo and engine room and the switch-board gallery. The disposition of the machinery in the other station is clearly shown in Figs. 3 and 4.

To meet increasing demands an additional 300 horse power Babcock & Wilcox boiler has been added to the Edison plant. One will supply steam to one 300 horse power cross compound Ball engine, which will drive a pair of 100,000 watt Edison machines. Another improvement will be the new 200 foot chimney with a capacity for 2,500 horse power of steam plant.

Only the arc lamps of the company and also those incandescent lamps supplied from converters will in the future take current from the old Paterson station. New contracts with the city and county have been recently consummated, covering a period of ten years. The outlying districts now lighted with 20 candle power incandescent lamps will be covered with at least 150 arc lamps. The company is under contract to complete this work by the first of October. For lighting the county roads there will be required from 150 to 200 arc lamps. To provide for the above the company will install seven 50 light dynamos and 300 double arc lamps. The company is also about closing a contract with the Paterson Street Railway company to furnish current for its electric line, which is now being equipped by the Field Engineering company of New York. This will require about 600 horse power in engines and four 100,000 watt dynamos.

Not considering the prospective railway work, the two plants with recent additions and contracts have a boiler capacity of 1,600 horse power, about 2,000 horse power of engines, and a dynamo capacity of 10,000 incandescent lamps, there being at present over 10,000 lamps in service. The above equipment, together with the fifteen 50 light [illegible] stations, representing [illegible] lights.

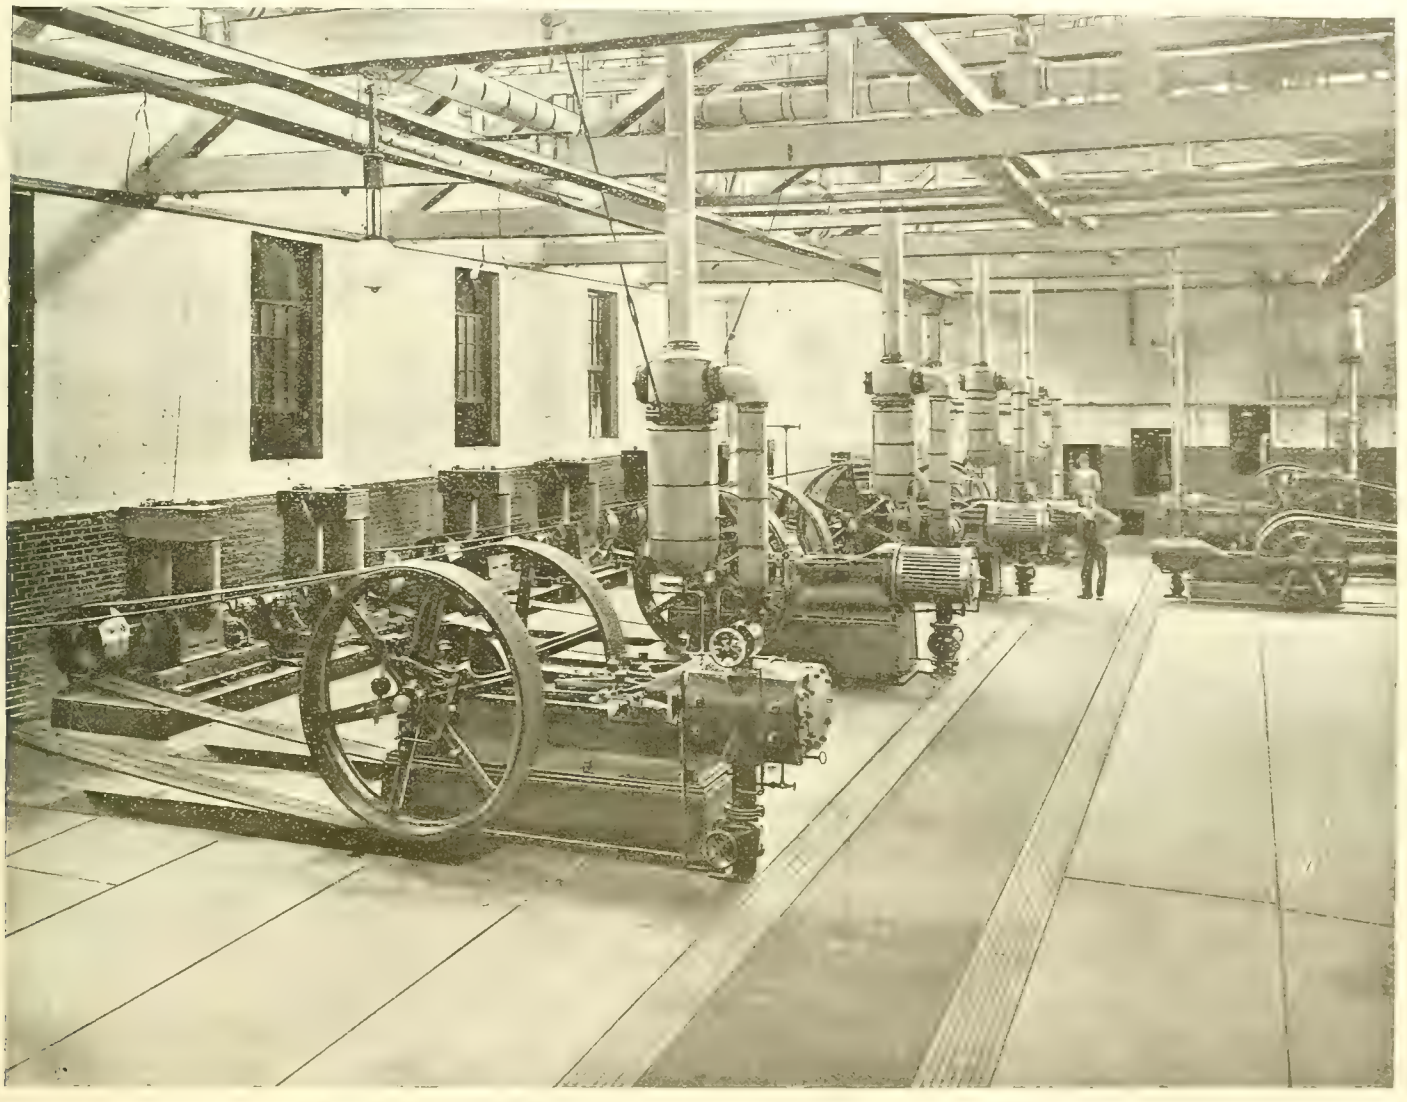

FIG. 1. THE STATIONS OF THE EDISON ELECTRIC ILLUMINATING COMPANY AT PATERSON, N. J.

Stopping an Engine by Electricity.

[illegible] wheel that turns the motive shaft driving the governor. The outer or belt wheel is journaled on a stud projecting from an arm pivoted to a lateral strut, the free end of the arm being connected to a link, which in turn is connected to a second arm, likewise pivoted, and whose free end is confined normally by a latch bar which holds the arm against the outward pressure of a spring. Adjacent to the latch arm is a magnet, which [illegible] pressing any one of the push buttons, draws the latch out of engagement with the arm, which flies outward, releasing the clutch pulley, allowing the governor to stop, and with it the engine.

The Ferranti System.

Mr. Ferranti stated at the meeting of the [illegible] Engineers, according to the [illegible] that high pressure electrical engineers could now guarantee that 95 per cent of [illegible] tion could be delivered, and [illegible] they could guarantee this, it was evident that in practice they could surpass this amount. It is stated that the Deptford [illegible] The districts around Blackfriars are being wired, and several installations are [illegible] mondsey. At Hayes, where [illegible] a complete new low tension network has been laid down and a new [illegible] horse power [illegible]

New York city has [illegible] stations, representing [illegible] lights.

Electric Power Transmission.[1]

L. F. L. Ewell

The most prominent modes of long distance transmission in use to-day, are: The steam, hydraulic, wire rope, pneumatic and electric systems.

For distances over one-half mile, or where power must be distributed to a large number of smaller machines, the electric system has been proven to be by far the most economical.

Steam can be transmitted economically for short distances only, owing to the large loss in condensation in long steam pipe lines, which are very expensive, both as to first cost and repairs; besides fuel is easily portable and a number of isolated steam plants in most instances can be operated cheaper than a large boiler plant, distributing steam through many thousand feet of steam pipe. If fuel is scarce and transportation high, the use of steam power, of course, will be unprofitable in either case.

Water power is portable only to a very limited extent. Mountains or steep grades may necessitate tunneling or the construction of very expensive canals. In the past manufacturers were, therefore, compelled to erect their factories, mills, etc., close to the river or falls instead of transmitting the water power to locations best adapted for their purposes. In many instances water power could not be utilized at all; for example, in mining, as, of course, the location of a mine could not be changed.

Wire rope transmission cannot be applied for long distances nor can it transmit great amounts of power. The loss by friction and the cost of maintenance of heavy cables are too great. It is claimed for the cable car systems in Chicago (which may be considered as an illustration of wire rope transmission) that their commercial efficiency is less than 20 per cent.; or, in other words, 80 per cent. of the engine power is wasted in keeping the cable in motion, while only 20 per cent. is delivered at the grip cars. No wonder electric street cars are taking the lead. They will eventually replace the cable system, except in a few instances as pointed out in Theo. P. Bailey's paper read before the Chicago Electric club, November 17, 1890.

Compressed air was until a few years ago the only method of transmitting power to great distances. In mining it was used almost exclusively. This power was used in the construction of the famous St. Gothard tunnel which connects the Italian railway systems with those of Switzerland and Germany. If such a tunnel should be built to-day, it may be safely said that electrical energy would be the agency. The main sources of water power in Switzerland are, as in the mountainous western states, characterized by small volume and great head, and could easily be used for driving water wheels of the Pelton or similar types coupled directly to electric generators.

Probably the largest pneumatic transmission plant in this country is near Marquette, Mich., which delivers at a distance of three miles 390 horse power as indicated at the engines at the Chapin and Ludington mines. This 390 horse power represents 27 per cent. of the horse power indicated by the compressors at the power station. The cost of this installation was about $500,000, the pipe line to be laid to a large number of smaller machines, the electric system is preferable. Instead of going into any lengthy arguments, a few paragraphs may be quoted from a letter dated Rock Island Arsenal, February 17, 1890, from J. M. Whittemore, colonel of ordnance commanding, to the chief of ordnance:

"The water wheels being connected in sets of four with generators, each generator will be able to transmit its electrical energy through a copper wire to anyone motor at any one time at any one shop, at a maximum loss of 60 horse power out of 200, giving 140 effective horse power to do the work.

"With the wire rope and rigid shafting transmission, this 200 horse power would not suffice even to move the shaft for doing any work in shops A and B.

"With a capacity of 700 horse power, which is all that

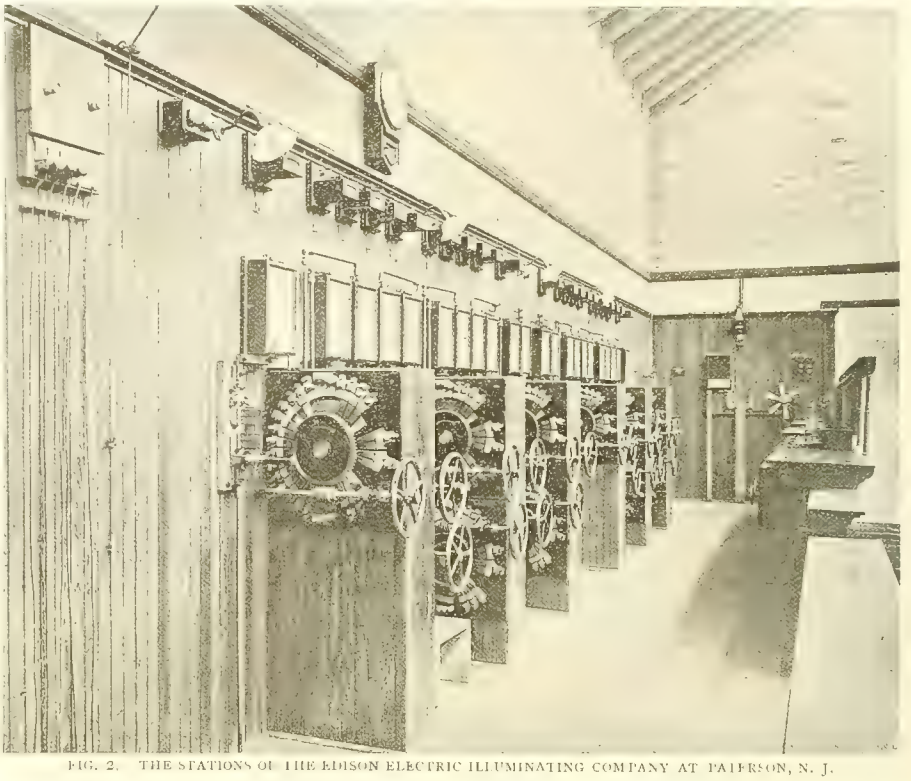

FIG. 2. THE STATIONS OF THE EDISON ELECTRIC ILLUMINATING COMPANY AT PATERSON, N. J.

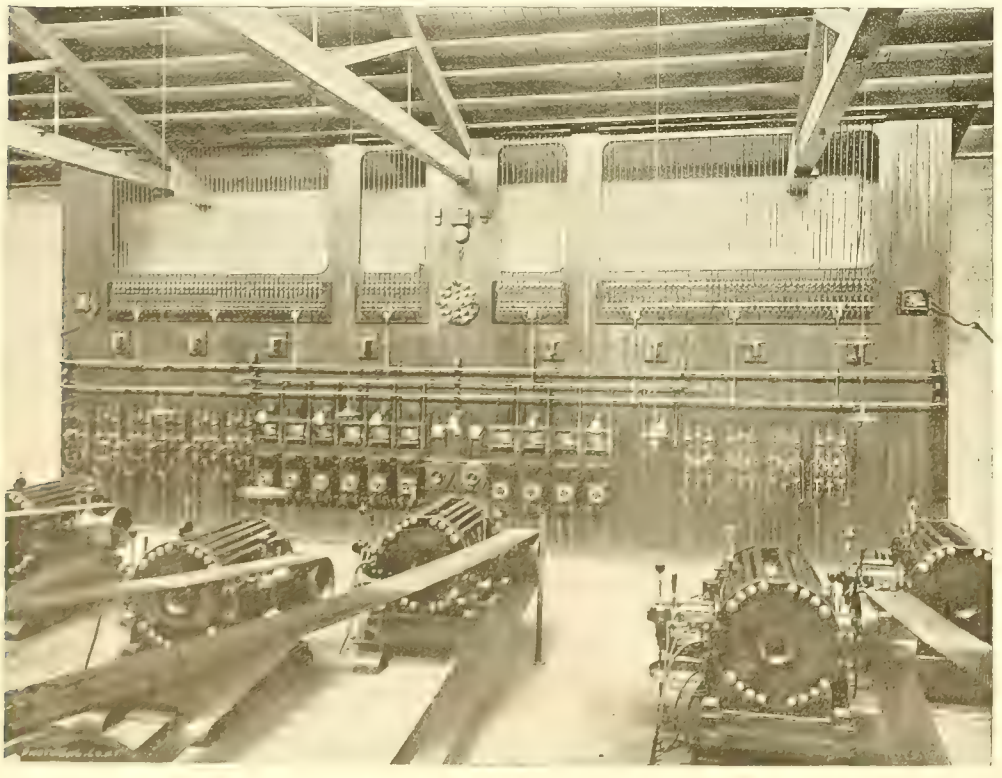

FIG. 3. [illegible]

Much more might be said comparing the different systems of transmission.

The main object is first, to answer in a plain, and, we hope, practical manner such questions as power-producers, and other prospective customers will ask electric manufacturers relating to power transmission; and secondly, to give practical rules and hints to engineers and motor inspectors in charge of transmission plants.

Questions often asked are:

Is electrical power transmission a practical and commercial success, and not a mere experiment?

What are the general advantages of electrical transmission over other systems?

To what distances may electric energy be transmitted, how many mechanical horse power can you recover at the motor shaft out of one hundred mechanical horse power delivered at the generator pulleys, and what percentage of electrical energy is lost in the conductors?

What is the approximate cost of generators and conductors to deliver power at various distances?

The first question can easily be answered by the following statistics:

On January 1, 1891, there were in use in the United States as nearly as can be estimated from statistics published since August, 1890:

In Central Stations:—

	Horse Power.	Capital Invested.
Arc and Incandescent Lighting	[illegible]	$128,000,000
Electric Railways	100,000	50,000,000
Stationary Motors on Independent Power Circuits	26,000	9,000,000
Total	522,000	$187,000,000

Isolated arc and incandescent plants are not included in the above figures.

Over half a million horse power is, therefore, generated every day throughout the United States to deliver electric energy over circuits from a few hundred feet to fifteen miles and more in length. Whether this electric energy is used for street cars, for stationary motors or for lighting, is immaterial; it is electric power transmission, pure and simple. Arc or incandescent lamps may be taken out of the circuit and electric motors substituted, and, *vice versa*, arc or incandescent lamps may be operated on any power circuit. It is generally known that electric street cars are lighted and heated by the electric current, which is taken from the wire conveying electric energy to the street car motors.

It is hardly necessary to say any more relating to the first question, whether electric power transmission is an experiment, considering the fact that over half a million horse power is generated every day and almost $200,000 000 invested for this purpose in the United States.

It has already been pointed out in a general way why electric long distance transmission is superior to other modes.

The electric transmission system is very flexible—it means in most instances an air line from power to motor; the conducting wires are cold and clean, they may be bent around sharp corners, and to the casual observer there is no evidence that they are conveying, possibly hundreds of horse power. Mining Engineer Browne of World's Fair Mine fame, who read a paper before the Chicago Electric club December 1, 1891,[1] explained most graphically the advantages of electricity in mines, and the drawbacks in long compressed air or steam pipe lines.

Steam especially is disliked by miners as it heats the mines, fills the air with moisture, and makes the problem of ventilation still more difficult.

New applications of electric transmission of power

1. [illegible]

are made almost daily, as is shown in the following quotation from the *Mining and Scientific Press* of San Francisco:

"In this day of steam, electricity and fast transportation in general, the motive power of the old canal—the mule—cannot be considered as a thing to be continued. In discussing the question now being agitated in Eastern Pennsylvania and New York in regard to the necessity for remodeling the motive power employed by the Washington & Cumberland Canal company, in view of the rapidly increasing coal and timber business crowding upon their line of transportation, the *American Manufacturer* says 'The motive power of the old canal—the mule—is not to be thought of. Steam offers but few more advantages, because it takes up so great a percentage of the carrying capacity of the boat, while the locks and the amount of help required stand in the way of using tugs. It was finally suggested that electricity should be used. The trolley system, by which small screw propellors could be run by electricity, was looked upon as the best solution of the problem. By using electricity the weight of the machinery to be carried would be small, and one man could control the motor and the steering apparatus without trouble. The plan is under serious consideration, and will probably be given a thorough test. If it prove successful, it may result in the restoration of abandoned canals and induce capital to seek an investment in new ones between points where heavy freights not requiring rapid transit, are shipped extensively.'"

Another application for electric transmission is that for irrigation. W. Forman Collins pointed out some time ago how vast areas now barren and worthless can, by this means, be made fertile and enormously enhanced in value. Mr. Collins refers in this connection to the report of Col. W. Tweeddale to the Kansas State Board of Agriculture.

It will be only a short time when the old dream of utilizing Niagara Falls for electric transmission will be a reality.

Before the application of electricity these power transmission schemes were never thought of. Only electricity enables man to transmit natural water powers economically to the places of application.

The three elements of electrical transmission of power are: (1st) The generators, which are placed at the power station and which are driven by the water wheel or steam engine or other prime mover; (2d) the copper conductors, which are placed on poles like telegraph wires, and which conduct the electric current from the generators to (3d) the motors, which deliver the electrical energy to all kinds of machinery. The motors are either belted or geared to these machines.

Electric generators are machines for converting mechanical into electrical energy, while electric motors reconvert electrical and mechanical energy.

The capacity of generators is therefore given by the manufacturers in watts or in electrical horse power, while the capacity of motors is generally given in mechanical horse power.

Hence in order to test these machines it is necessary to have electrical instruments (ampere meter and voltmeter) to measure the output of the generator in electrical horse power, while the output of the motor should be measured in *mechanical* horse power by means of a dynamometer.[1]

In practice, however, engineers often measure the electrical horse power delivered at the motor terminals and then deduct a certain percentage to get the rating in mechanical horse power.

Ordinarily electric manufacturers allow for motors up to 20 horse power 1,000 watts per mechanical horse power, indicating 75 per cent. efficiency of the motor; from 20 to 50 horse power, 900 watts per mechanical horse power, indicating 83 per cent. efficiency of the motor; over 50 horse power, 830 watts per mechanical horse power, indicating 90 per cent. efficiency of the motor.

A similar rule will hold good for generators. Up to 20 horse power the output in electrical horse power will be about 75 per cent. of the mechanical horse power applied to the pulley. From 21 to 50 horse power the output in electrical horse power will be about 83 per cent. of the mechanical horse power applied to the pulley. Over 50 horse power the output in electrical horse power will be about 90 per cent. of the mechanical horse power applied to the pulley.

Seven hundred and forty-six watts (one watt = ampere × volt) equal one electrical horse power. If we therefore deliver, as in the example mentioned, 1,000 watts—1.333 electrical horse power—to the motor, and the latter has a commercial efficiency of 75 per cent., it will deliver 75 per cent. of 1.333=one mechanical horse power at its pulley.

Or, if we deliver one mechanical horse power to the pulley of a generator of 90 per cent. efficiency, the electrical output will be 90 per cent. of one electrical horse power, or .9 electrical horse power, or .9×746=671.4 watts.

It is only fair to state that machines of the best makes will show higher efficiences, but these figures may be considered as a conservative estimate.

In the following there will be assumed both for generator and motor a commercial efficiency of 90 per cent. or a loss of 10 per cent. in conversion.

1. The standard dynamometer is a Prony brake, consisting of a belt around the driven pulley, one end of which is attached to a spring balance, the other end to a weight. The difference between the two readings gives the pull exerted by the belt, and this multiplied by the velocity of the belt gives the power absorbed by the brake. The ratio between this power and the power delivered to the pulley by the motor is the efficiency of the latter.

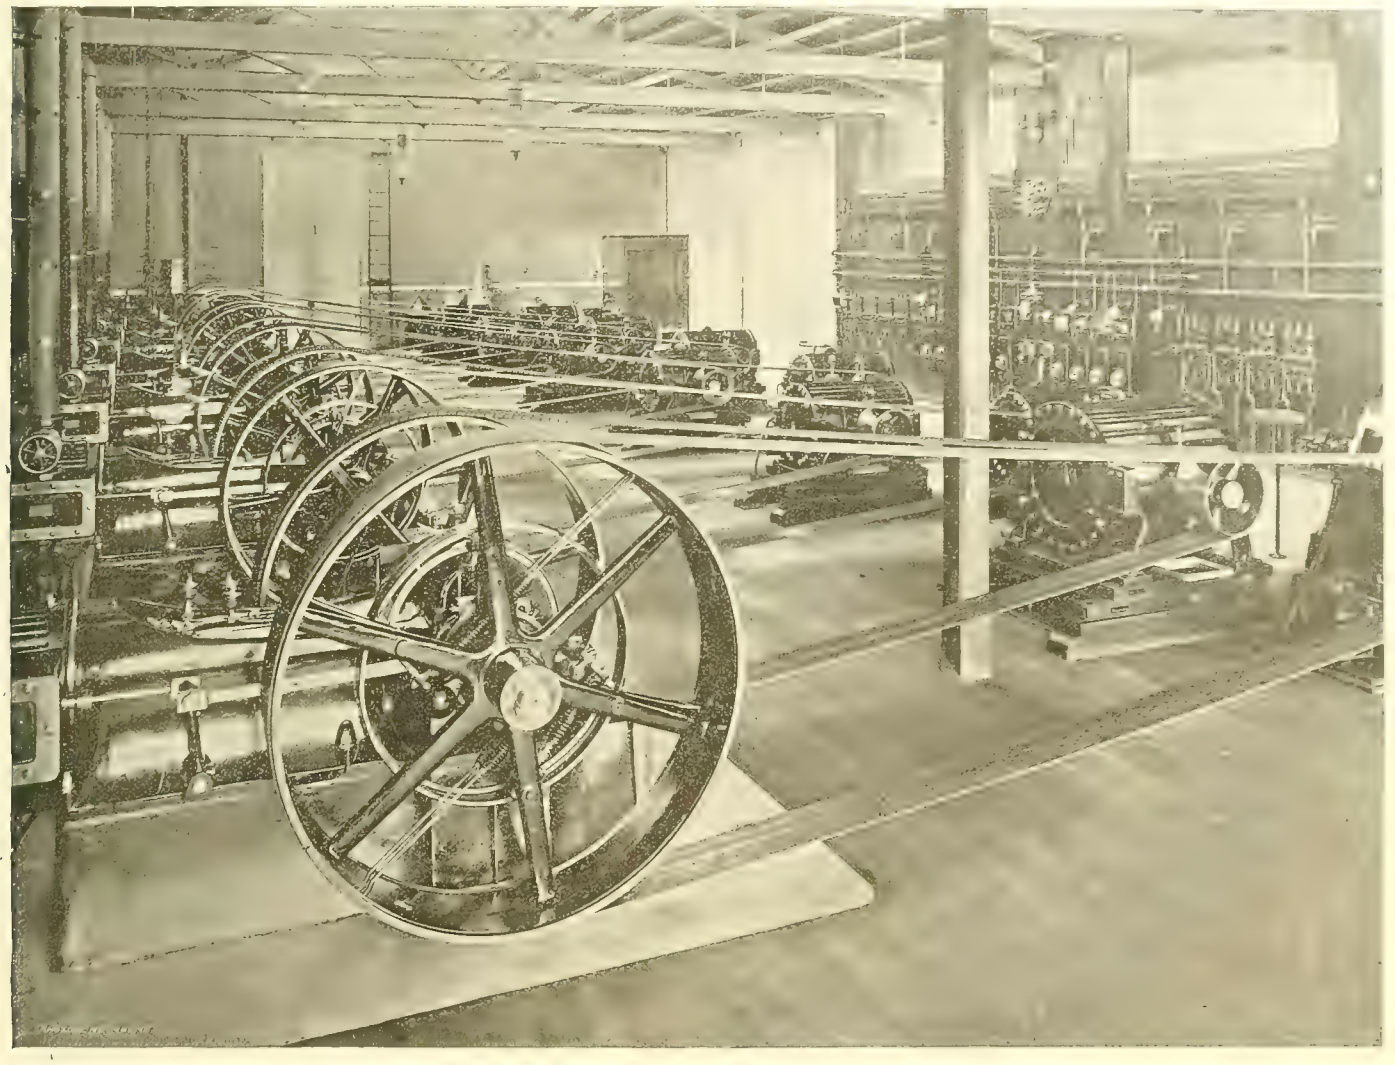

FIG. 3. THE STATIONS OF THE EDISON ELECTRIC ILLUMINATING COMPANY AT [illegible], N. Y.

This efficiency of a couple of electric machines connected as generator and motor, including the connecting conductors, is often called the "couple efficiency."

In practice the generator and motor are so far apart that there is a loss of electrical energy in overcoming the resistance of the conductors. This loss depends upon three factors, viz.: distance, pressure at generators, and size of copper conductors. For a given case the first factor, distance, is constant; pressure and size of conductors are variable at will; therefore, the loss in the conductors is a variable percentage desired.

It should be stated that only "complete metallic circuits" will be considered, or, in other words, it will be assumed that the generator is connected to the motor by means of two conductors. "Earth returns," which are much used in electric railway work, will not be considered.

If a "couple efficiency" of 81 per cent., a loss of 10 per cent in the conductors is assumed, there will be:

[illegible]

Or the commercial efficiency of the whole system from generator pulley to motor shaft would be almost 73 per cent.

The city council of Salem, Va., has granted [illegible] to the Salem Street Railway Company [illegible] to the property of the [illegible] the south side of [illegible] to extend this line [illegible] the lands of [illegible] city of Roanoke [illegible]

and if New Yorkers hope to have an efficient system of surface roads they should take advantage of the experience of their neighbors.

BROOKLYN, which has been the scene of a bitter controversy over the electric railway question, will have a trolley system after all. The State Board of Railroad Commissioners has finally decided to allow Deacon Richardson to build twelve miles of electric road. When the people of Brooklyn realize the advantages of the electric system there will be little opposition to extending the service and the entire city may shortly have electric cars.

RAPID transit in New York city does not appear to be as near solution as was at first hoped. The second report of the commissioners is discouraging to those who desire the adoption of a system that will provide for the future. It appears that the commissioners have not fully appreciated the needs of the city, and the measures suggested by them will undoubtedly prove inadequate unless radical changes are made.

THE question of electric power transmission to which considerable space is devoted in this issue is one of the most important problems with which the electrical engineer has to deal. In this country especially the subject is already assuming great prominence, and it is becoming more important every day. The rapid development of the electric railway has occupied the attention of a large proportion of those interested in power transmission, but now the application of electricity to mining bids fair to assume equal importance. Each week brings additional evidence of the confidence of the mining companies in electrical apparatus. The water powers in this country which have long been permitted to go to waste are now being utilized, for generating electric power. The article presented elsewhere will be of special interest to all who are engaged in this department.

THE controversy over the accumulator patents was practically ended last week, when Judge Coxe of New York handed down a decision upholding the patents of Charles F. Brush. The action under which this decision was given was between the Brush and Accumulator companies, but as the old Julien company has control of the Brush patents the decision is a victory for that company over its old rival, the Accumulator company. Judge Coxe awarded Brush the honor of being the inventor of the present form of accumulator. The result of this controversy will no doubt result in the development of a first-class storage battery system. Pending the decision accumulator companies held back, evidently fearing to invest heavily in expensive plants. They were unwilling to put money into the business until the patents had been sustained. Now that a decision has been secured it is not unlikely that great advances will be made, and an effort made to introduce a storage battery system that will be both practical and economical.

IT seems that over in Buda Pesth, Austro-Hungary, they are seriously considering the question of using electric power to drive light machinery. An Austrian correspondent of a London technical journal tells how the project is being gravely discussed: "The management of the Buda Pesth city railway," he writes, "has been seeking permission for some time past to supply electrical power to private persons for industrial purposes. The chief city engineer is of opinion that the supply of electrical power would be very advantageous in the carrying on of small industries. He states, moreover, that the electrical central station is quite sufficient for the working of the railway and for supplying power to private works. This would be the case even if the railway were to be further developed, since the central station can be enlarged." The naivete of the last sentence is delicious. Here in Chicago, where hundreds of electric motors attached to central station circuits are employed to operate light machinery of all kinds, it seems strange that the feasibility of such installations should be debated. And it is stranger still that the question should be raised in such a progressive and enlightened city as the new underground conduit electric railway shows Buda Pesth to be.

STREET railway managers in this country have been watching with interest the proceedings of the Toronto officials who have been negotiating street railway franchises. It will be remembered that at the expiration of the thirty-year [illegible] company recently the city assumed [illegible] and it was announced [illegible] the operation of the road [illegible] that the best terms [illegible] suggestion for the disposal of the [illegible] to take one of the companies which endeavored to secure control. Charges of bribery were openly made last week, and a press dispatch says that an ex-alderman applied for an injunction to restrain the city council from entering into an agreement with the Everett company, alleging that the recommendation of the Street Railway committee to award the franchise to the Everett company was procured by dishonest and corrupt means. It appears that the city fathers of Canadian municipalities resemble American aldermen in this respect. The people of the city of Toronto should need no further evidence of the danger of permitting great public enterprises to be controlled by irresponsible bodies of politicians who grasp every opportunity to secure boodle. It is well for the city of Toronto that this example has been brought before the public, and other cities should profit by it too.

JUDGE COXE said in his opinion on the accumulator patents that "the nomenclaturist should not seek the reward for his labors in the patent office. A person is not entitled to a patent because he has invented a new word." Many of the patent office examiners evidently take a different view of the case. They believe, it would seem, that where there is much legal verbiage which they do not understand, the applicant must be deserving of a patent. In the case in point several claims on several patents were allowed by the examiners, which were practically covered in one claim. It is these things that bring the patent office into disrepute and make patents in this country worthless until they have been sustained after long and expensive litigation. We have on several occasions called attention to this matter. In our issue of Aug. 16, 1890, nearly a year ago, we alluded to a most ridiculous example afforded by the patent office, which issued two patents on the same "invention" to two applicants. These patents were issued the same day. At that time we said: "The patent law is becoming too attenuated when one who invents a coating of conducting substance, 'in which the conductivity decreases from one place upon the surface to another,' may be prevented from using an exactly analogous 'conducting substance which gradually decreases in breadth from one point to another.' We submit that it is not invention, but a mere change of form or modification which any mechanic could make without the exercise of inventive faculty. In short, we contend that patents should be issued for inventions and not for mere forms of expression—slight, meaningless verbal changes."

Judge Coxe's decision strongly supports the position we assumed at that time. He seems to be thoroughly impressed with the idea that there is too much hair splitting at the patent department, and too little common sense employed.

Electricite, an electrical journal published in Paris, has fallen into a grave error in construing some of the criticisms made in this paper on the Construction Department of the World's Columbian Exposition. "The WESTERN ELECTRICIAN," it says, "has now laid down its arms and announces that the exposition, of which it has hitherto been an eager supporter, will be a fiasco." We have done nothing of the kind; and, unless the misrepresentation has been intentional, we shall be grateful to our French contemporary if it will do what it can to rectify the false impression it has created. We have perfect confidence in the overwhelming success of the World's Fair in general and of the display in the Department of Electricity in particular. We have had occasion in the past, and may have again in the future, to point out mistakes committed by the Construction Department in the preliminary work; but it has never occurred to us to doubt for an instant the complete success of the fair. Indeed, our contention has been so much the reverse that we have held that the electrical building, as planned by the architects, was only about half large enough for the demand that we foresaw would be made on its space. How can that position be reconciled with the statement that we predicted failure for the exposition? The idea is absurd. We have always said that the electrical display would be a grand one in any event, adding that the electrical fraternity would, however, take hold of the matter of making exhibits with greater enthusiasm and in a better spirit if their reasonable demands were complied with. As Chief Barrett remarked a short time since the difficulty will not be to get exhibits but to find a place to put them. Our friends in France should bestir themselves and send over their applications for space at once unless they wish to occupy a position very humiliating to their national pride. Neither should they let the McKinley bill act as a bugbear. Whether that much-discussed measure is beneficial or mischievous in principle, it certainly has little or no effect on the electrical interests of France and the United States. So there is nothing to prevent and everything to encourage the French electricians in making a fine display in Chicago in 1893.

Improvements in Steno-Telegraphy.

Considerable advancement has been made of late in perfecting a system of steno-telegraphy which, it is hoped by those engaged in the experiments, can be substituted for the Morse system. It is claimed that recent improvements in this line have made it practicable to transmit 150 words per minute, delivering a typewritten message.

In the accompanying cuts is illustrated a system devised by M. Cassagnes, which has been in practical operation some time between Paris and Marseilles. M. Cassagnes has devoted most of his time to this system since 1886, and

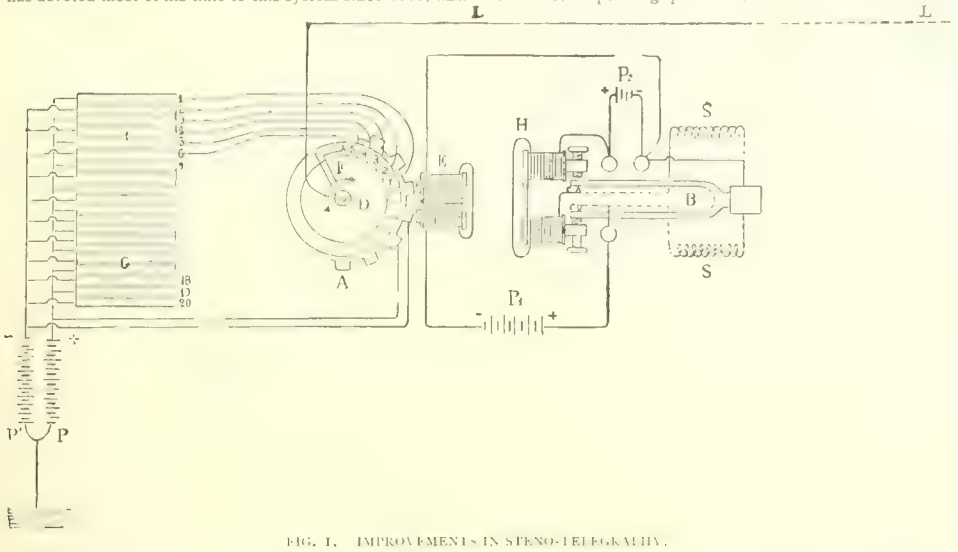

FIG. 1. IMPROVEMENTS IN STENO-TELEGRAPHY.

he has now succeeded, he announces, in presenting a complete system for commercial work. The recent improvements have greatly facilitated operations, and permit great rapidity in manipulation.

The transmitter for the system consists of a keyboard of twenty keys, each of which represents a phonetic sound. These twenty signs are all that are required for any modern language. The receiver is constructed in a similar way, and each of its keys terminates in a steel engraved type, the impression of which is received on a paper tape, moving automatically with the operation of the instrument. It is claimed that by means of this instrument as high as 200 words per minute can be transmitted. In the original system a cable of 20 wires was used for connecting the transmitter with the receiver, but by adopting the LaCour phono-wheel only one wire is required between stations.

In Fig 1 *CC* is the keyboard of the transmitter. Each of the twenty keys is alternately connected to the positive and negative pole of two batteries P^1 and P^2, the opposite poles of which are joined to the ground. From the keys extend wires to fixed contact points 1, 2, 3, etc., placed on an insulating desk *D*. Above the rotating phono-wheel and on its vertical axle is mounted a sliding contact *F*, from which connection is made to the line. When key number 6 is pressed down, as shown in the illustration, it will be seen that connection is made with the line at the instant only when the brush *F* passes over the point 6. As the two rotating brushes are synchronous the impulse of the current will pass from point 6 in station one to point 6 in station two, thence to relay 6 and to ground.

A local battery P^3, Fig. 2, is closed through contact *V*, relay 6 and through a corresponding magnet in the receiver, which attracts the key lever and makes this strike against the paper tape. *G* is a drum for holding the tape, and *M* is a magnet joined in the outgoing battery wire *V*, and operating a lever which releases a tape winding device.

The phono-wheel, which is the vital point of this system, is the invention of Paul LaCour of Copenhagen, and consists of a horizontal wheel *A*, Figs. 1 and 2, of soft iron, having teeth cut in its circumference, and turning on a vertical axle. On the top of the wheel is a cylindrical box *Q*, Fig. 3, filled with mercury. In front of the wheel is an electro magnet *E*, Fig. 2, receiving an intermittent current from the battery P^1. When current passes through the magnet it will attract the nearest tooth of the wheel, and during the interruption of the current the wheel passes on, so that the next impulse of current is brought to bear upon the next tooth of the wheel, and thus keep it in constant rotation. The interruption of the current is obtained by means of a tuning fork *B*, which opens and closes a pair of electric contacts for each oscillation. One of these governs the circuit and electro magnet *E*, and the other the electro magnet *H*, which serves to maintain the vibration of the fork. Fig. 3 gives a perspective view of the instrument.

When the wheel is set in motion by hand it will continue to rotate, the speed depending on the number of teeth in the wheel and [illegible] the wheels at the two stations are exactly alike, and the tuning forks have the same tone, the oscillation of both and consequently the rotation of the wheels will be the same even at a great distance [illegible] is perfect, and as the slighest variation in the conditions described will result in one wheel dropping behind the other, an automatic regulating device is provided. In Fig. 1 two regulator wires extend from the two poles of the battery *P* and P^1 to two blank contact points on the distributer *D*. A corresponding point on the distributer of the receiver station is connected to a polarized regulating relay *R*, Fig. 2. When the speed of the wheels becomes uneven the brush on the transmitter will pass over either the positive or negative contact the same instant the receiver brush

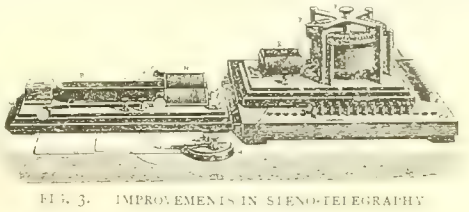

FIG. 3. IMPROVEMENTS IN STENO-TELEGRAPHY.

is in contact with the regulating relay. This device will then be actuated, the armature will be drawn either right or left, cutting in or throwing out resistance in the circuit of the vibrator magnet *H*, decreasing or increasing the magnetic force, and consequently the vibration of the tuning-fork.

The keyboard of the receiver has been greatly altered of late, and important improvements introduced. Instead of using signs indicating phonetic sounds the common alphabet has been applied, and the construction of the receiver changed, so that by pressing two, three or four keys at once a full syllable of a word can be transmitted and impressed on the paper tape in a single rotation of the phono-wheel. Fig. 4 is a detailed view, and Fig. [illegible] of this instrument. It consists of twenty electro magnets, [illegible], etc., each of which is mounted with an armature lever, and the spool has passed [illegible] brushes of the distributer make 100 turns per minute, as on the line between Paris and Marseilles [illegible] will transmit [illegible] words a minute [illegible]

The [illegible]

tion. When current is passed through one of the electro magnets *E* it attracts its armature and releases the corresponding sliding bar, which is drawn toward the printing wheel [illegible] screw *V*. The printing wheel, which has also been released, turns until the sliding bar strikes against a tooth in the eccentric cam-wheel *S*, the distance which the wheel has advanced, or the distance from the tooth to the center of the arbor, will correspond to the stroke of the bar, and this again depends on the number of bars which are released simultaneously. The letter which in this instance is on [illegible] impression on the paper. A second arbor *C* with an eccentric disk operates a series of levers, which releases the printing wheel, presses the tape carrier against it, and finally replaces the sliding bars in their original position. *I* is an [illegible] the paper tape.

With this instrument it is possible to send a telegram with the speed of a stenographer, and to receive it as a printed message at the same rate of speed. The saving in time effected by this system is apparent. A stenographer will require about six hours to write down the notes he has taken during one hour. With the Cassagnes system it is claimed that the same work can be accomplished in one or two hours. For systematic service the inventor has applied a puncher, together with an automatic transmitter, to take the place of the keyboard in station one. A paper tape is passed through a perforating instrument manipulated by the operator, and having twenty buttons, each of which is fastened to a lever terminating in a smaller steel punch placed in a vertical row, these punches corresponding to the signs of the keyboard. The paper tape is perforated near its border for the purpose of guiding and advancing the paper when placed in the transmitter. When thus prepared the tape is taken to the transmitter, where it passes under two smaller cam-wheels. Whenever a perforation is encountered a lever slips through and makes a contact. The impulse is transmitted over the distributers to the receiver at the next station, and recorded as a typewritten message.

By this arrangement of automatic transmission the reliability of the instrument is claimed to be almost perfect,

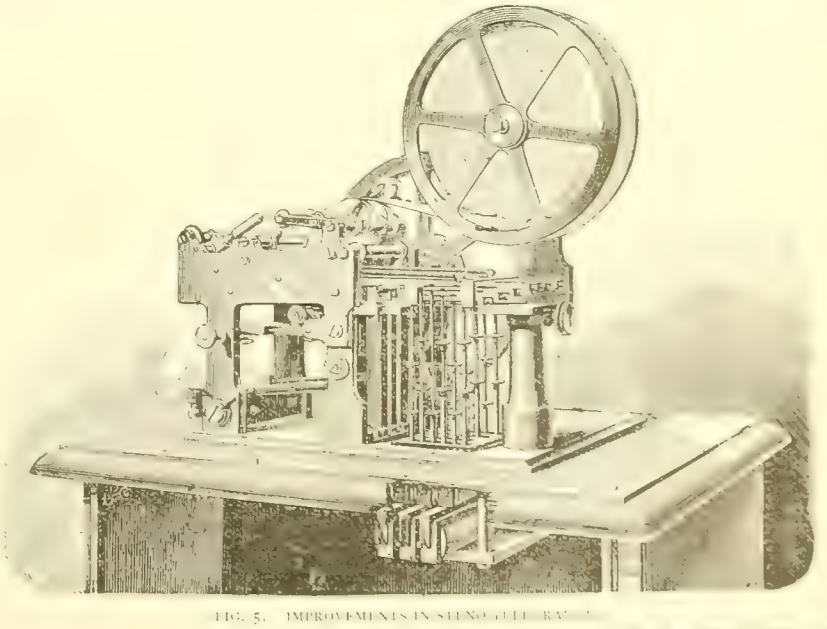

FIG. 5. IMPROVEMENTS IN STENO-TELEGRAPHY.

[illegible] an electric light plant at Ellicott City, Md.

Thomson's Method of Measuring Electric Currents.

The accompanying cut shows a vertical section of a device designed by Elihu Thomson for measuring electric currents. Heat is generated by the current to vaporize a liquid, the amount of vaporization indicating the electricity employed. This may be ascertained by condensing it in a suitable chamber and measuring the amount condensed.

In the cut B is a bulb or receptacle of glass or other suitable material containing alcohol A or other vaporizable fluid which has been well boiled in the bulb in which it is sealed while the vapor is escaping, thus producing in the space above an alcohol vapor at the tension due to the temperature as no air is present.

Within the bulb is an electric conductor H, connected with outside conductors by wires sealed in the bulb. This conductor may be of platinum wire of small gauge, so as to be readily heated by the current. N is a sheath or cover for the bulb and is designed to prevent the escape of heat. The vapors produced by the heating of the liquid pass from the receptacle to a chamber B^1, in which they are condensed and collected as liquid. By means of a suitable scale applied as shown the amount of liquid condensed may be noted.

The Montreal Convention.

The citizen's committee of Montreal is active in making arrangements for the National Electric Light association convention in September. At a recent meeting it was stated that the finance committee of the common council had recommended an appropriation of $2,000. It was decided to give a conversazione at McGill college, and many other forms of entertainment were discussed.

Chairman Gulick of the committee on exhibits has issued a circular to intending exhibitors giving the following information:

It has been found, in order to carry out the plans formulated by this committee, that the general expenses of the exhibition, namely, rent, flooring of a portion of the rink, lighting, music, attendance, superintendence and miscellaneous expenses, will amount to a total of $4,500. This estimate is the result of a careful consideration of several gentlemen who have had a large experience in exhibition matters, and has been made liberal. Assuming as a basis the above expense, and dividing by the total exhibiting space, the cost per square foot has been obtained, which amounts to 30 cents. This has been fixed upon, therefore, as the charge for space. You can therefrom readily arrive at the total charge to you for the above mentioned items. In addition to this, we wish to call your attention to that clause of the rules and conditions noted in the application blank which you have filled out, under the head of "Care of Exhibit," which reads as follows:

Exhibitor must take charge of and care for [illegible] space during the [illegible] and [illegible] expenses on account of [illegible]

One-half of the charge for space is payable upon acceptance of the awarded space, and the balance not later than the 1st of September. Should it be found at the close of the exhibition that the expenses amount to less than $4,500, Bovey, kindly offers several hundred horse power at a cost of operating expenses. For small powers, such as for motor, or other work, it is expected that an arrangement can be made for obtaining the same from the plant of the Windsor hotel, adjoining the exhibition building.

We have had applications for much more than half the available space, and, in addition, applications which bring the total of the space applied for much in excess of that available. An entrance fee of 25 cents willbe charged, but complimentary tickets will be issued at the request of the exhibitors. Arrangements have been made for the admission of all goods in bond, and the exhibition building

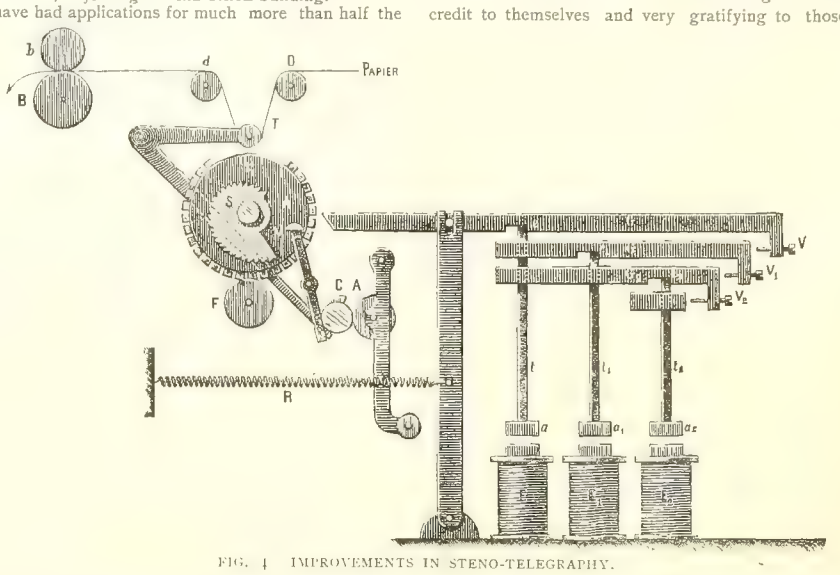

FIG. 1 IMPROVEMENTS IN STENO-TELEGRAPHY.

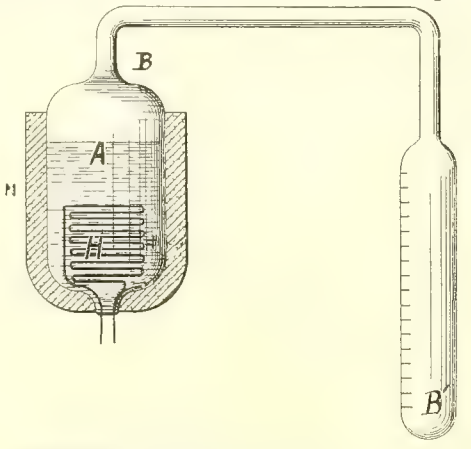
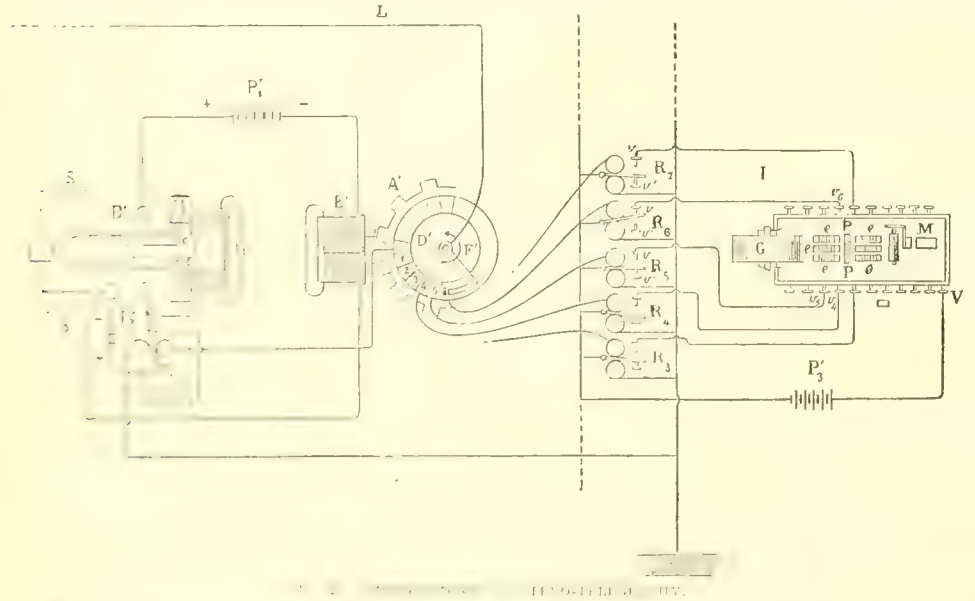


THOMSON'S METHOD OF MEASURING ELECTRIC CURRENTS.



[illegible] be constituted a temporary bonded warehouse. Duty to be paid only in case of sale. Ample space adjoining the building has been secured for the storage of packing cases without charge.

[illegible] to proceed at once [illegible] the space [illegible] to rising [illegible] to make [illegible] The good [illegible] in this [illegible] the fact that [illegible] the first place [illegible] any other convention exhibition, yet the applications for space have been in excess of that available. With the cordial support that the management has had there is now no question that the association and the exhibitors will make a showing that will be a credit to themselves and very gratifying to those who have the true interests of electric lighting at heart.

It is hoped that the governor-general of Canada will open the exhibition, starting the machinery in motion. Plans will be made for music afternoons and evenings, special features in decoration will be carried out, and the Canadian members of the committee on exhibits promise great interest from their countrymen and a very large attendance. In view of the many new and pleasant features which will distinguish the convention, a very large number of the members of the association propose to attend the convention with their families, and already the hotels of Montreal are flooded with applications for rooms

New Railway Management for Detroit.

The rumors which have been freely circulating in Detroit for the last week are fully substantiated in the announcement of the purchase of the Detroit street railway and Grand river avenue lines to a syndicate composed of Boston and New York capitalists, headed by ex Gov. Waller of Connecticut and Williard B. Ferguson of Boston.

These two gentlemen have been in Detroit for some time quietly carrying on the negotiations which led to the completion of the transfer and its public announcement last week. It appears that offers were made to Mr. Hendrie, the president of the company, in May last, but that these offers were refused at the time. Shortly after this the company suffered somewhat from a strike of its employes.

At the close of the strike the negotiations which had been temporarily suspended were resumed. Aided by the discontent manifested by the citizens against the old horse system, the new synd'cate was successful in buying out the old stockholders. Both parties to the transaction decline to reveal the sum paid; but it is learned from reliable sources that the price asked by the street railway companies was $5,000,000, which was finally reduced to $4,500,000.

Gov. Waller is reported as saying that the new company will give rapid transit to Detroit, without further delay. It is stated that the Fort Wayne and Elmwood line is not included in the deal, but that the purchase does cover the Highland Park electric road. The new company contemplates bringing every line in the city under one management. The system includes about eighty mites of road.

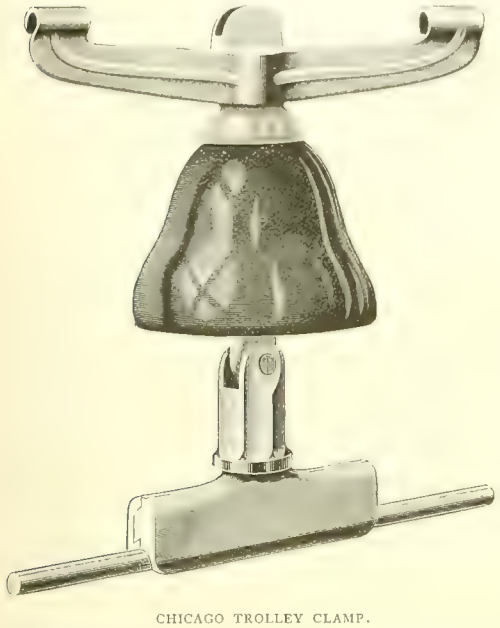
S. Harrison Wagner, a partner of ex-Gov. Waller, says the consideration was more than $5,000 000. The change from animal to electric power will throw 2,300 horses on the market.

Bell Telephone Stock.

A special dispatch from Boston to the *Chicago Tribune* states that the bears created a rumpus on 'Change on July 24th, attacking Bell Telephone stock so savagely that it dropped from 183 to 175. Then the bulls rallied and forced the price back to 178. It was rumored on the board that the drop was occasioned by the alleged discovery that the company was in the market trying to borrow money, but a conservative lawyer, who is an attorney for the company, was among the buyers, brokers were not inclined to place much reliance in the rumor. It seems to be the general opinion that the decline was due to tired holders of long stock. The Bell Telephone company made a net gain of 61 instruments for the month ended July 20th, against 1,900 for the same period in 1890. Since Dec. 20, 1890, the net gain of instruments has been 4,149.

Chicago Trolley Clamp.

The accompanying illustrations show a new trolley wire clamp devised by John S. Curtin, purchasing agent for the Electric Merchandise company, Chicago. The clamp is formed in three distinct parts, having two sections with opposing lips, one of which is provided with a threaded projection upon which the clamping nut is screwed, the other having a dog inclosed by the protruding lower rim of the nut. Through the lower portion of these opposing sections, a grove is formed to contain the trolley wire, the

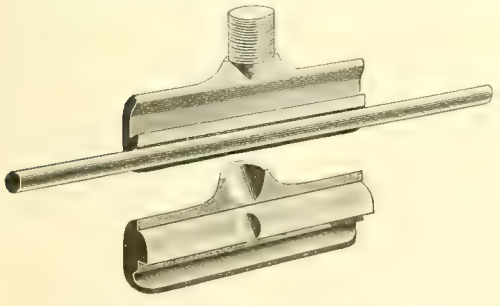


CHICAGO TROLLEY CLAMP.

size of which does not call for a different construction of the clamp. The opposing lips are cut at such an angle that they still engage each other when the largest trolley wire is inserted in the groove. The screwing down of the nut upon the threaded projection and over the dog causes the lips to slide one within the other, thus forcing together the lower sections of the clamp upon the wire, preventing all possibility of falling. The movement of the wire from expansion and contraction is provided for in the hinge joint included in the nut. With this clamp it is claimed that an absolutely reliable support is provided for the trolley wire, while at the same time its simple mechanism makes its adjustment at any place upon the wire, or entire removal therefrom, an easy task. The clamp is said to be equally efficient whatever may be the style of insulator used. The Electric Merchandise company, Chicago, is sole agent for this device.

Claims an Interest in Edison's Inventions.

A press dispatch from Boston says taht Judge Nelson has made and important order in the arguments presented recently in the suit against Thomas A. Edison in the United States Circuit Court. This action was begun in 1883 by E. Baker Welch, who asked $250,000 damages on the strength of a contract made between him and Mr. Edison



CHICAGO TROLLEY CLAMP.

in 1869, which Welch claims entitled him to one-half interest in Edison's inventions. The court rules as follows:

"As to further answers to interrogatories, denied; on production of books and writings, ordered that plaintiff file originals or copies of all communications from defendant or between plaintiff and Milton F. Adams, Jr., or Charles Williams, Jr., and of all receipts, promissory notes or contracts exchanged between plaintiff and defendant, and also that plaintiff produce all books of account showing money payments between the parties. As to the bill of particulars, ordered that plaintiff file a statement of all patents, inventions, improvements, instruments, principles, methods and systems of defendant in which plaintiff claims an interest. The motion to amend answer is allowed. The motion for auditor is to stand for further consideration after the [illegible] shall have complied with the order of the court.

A New Insulating Joint.

Numerous devices have been designed for insulating combination fixtures from the connecting gas pipes, but it may be said many of these have been more ingenious and complicated than practical. The Wirt joint shown in the illustration is extremely simple, having only two parts which are securely fastened together by a hard insulating compound. There are no screws or loose pieces. It is made by the Electrical Supply company, 161 Madison avenue, Chicago.

Prominent Asbestos Manufacturers Consolidate.

The H. W. Johns Manufacturing company and the Chalmers-Spence company, New York; the Asbestos Packing company and Chas. W. Trainer & Co., Boston, and the Shields & Brown company of Chicago, the five largest asbestos manufacturers in the United States, have formed a corporation under the name of the H. W. Johns Manufacturing company, to control most of the output in their line of business. The officers of all the companies and their chief employes will remain with the new concern. H. W. Johns is the president; R. H. Martin, formerly president of the Chalmers-Spence company, the new vice-president; C. H. Patrick, treasurer, and G. P. Erhard, secretary, both of the last two named having previously been with the H. W. Johns Manufacturing company. The H. W. Johns Manufacturing company was the name chosen for the new corporation because the old company of that name was the pioneer in the business, and had besides the largest factory. H. W. Johns began the manufacture of asbestos goods in 1858. Englishmen took their cue from him and have set up asbestos factories, but American manufacturers export their goods to Great Britain and elsewhere in Europe in considerable quantities. The factory of the old H. W. Johns Manufacturing company at the foot of Thirty-ninth street, Brooklyn, N. Y., is already the largest one devoted to the manufacture of asbestos goods in the world; about 125 men being employed. A new building will shortly be erected which will employ double that number. Factories will also be run in Chicago and Boston. The old H. W. Johns Manufacturing company also made asbestos fire and water-proof paints and roofing,

NEW INSULATING JOINT.

an important branch of the business, while the other concerns confined themselves solely to the manufacture of asbestos steam pipe and boiler coverings, steam packings, fire proof cements, fabrics, ropes and twines. The new company will also be sole agent for the sale of Vulcabeston, which is used largely for electrical purposes in the manufacture of switch-boards, armature sleeves, battery cells, and insulating parts for arc and incandescent lights, motors, etc. The new H. W. Johns Manufacturing company will have headquarters at 87 Maiden Lane, New York City. There will be branch offices in Boston, Chicago and Philadelphia, and agencies in London and elsewhere abroad.

New Porcelain Insulator.

The accompanying cut illustrates a porcelain insulator of new design. The slot around the base of the insulator, inclining downward, effectively prevents any moisture covering the insulator from the conductor to the supporting base. These insulators are highly glazed, with a counter-sunk base. They have given satisfaction to those who have used them. They are being placed on the market by the Central Electric company of Chicago.

Chilian War Affecting Telephone Interests.

A recent number of the London *Electrical Review* contained an abstract of the last directors' report of the Chili Telephone company, Limited, covering the affairs of the company up to April 1st last. The report contains several interesting references to the civil war in that country, as will be seen by the following extracts:

"After the outbreak of the civil war the business of the company was stopped by the order of the government, which has since had the entire use of those of our lines situated within the districts remaining under its control; but business has been resumed for the public at Iquique and other stations in districts held by the Congress party. On the 31st of March, when the present account ended, the public service at Santiago had been suspended for one month and eighteen days. For the loss of business the government will compensate the company, and $62,000 had on the 31st of March been received on account of such compensation.

"The company's property has sustained damage only in

authorities."

[illegible] for the [illegible] paid-up capital, as against a distribution of 5 per cent. for the previous year.

NEW [illegible]

with very indefinite prospects of its ending—and also in view of the fact that for capital purposes it has been necessary to use, temporarily, the income of the company until the capital exchequer be replenished by further issue of securities—which cannot be done on satisfactory terms at the present time—the directors recommend that no dividend be paid, carrying forward undivided the whole balance of £14,209 10s. 1d. until peace is re-established, and the future of the company becomes more secure

"The company is now in sole possession of the whole field. Its system is already in far better order than ever before. It has established new exchanges throughout the country, and its prospects—but for the revolution—are brilliant."

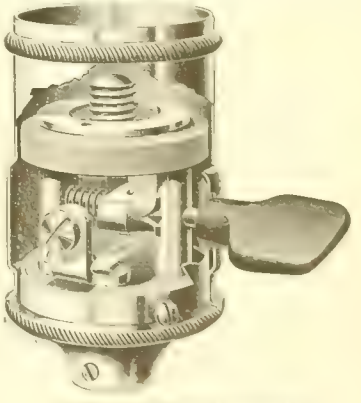
New Incandescent Socket.

The accompanying cut illustrates the new incandescent socket of the Union Electric Manufacturing company of Bridgeport, Conn. The device has been received with much favor, and the company is making a specialty of it. There are very few parts to it, the chief novelty being the method of holding the key in position by peculiarly shaped projections on the key, pressed up against one of the frame posts by a spring. In the most recent form the contact ring on the top is done away with, and two screws are substituted, one going into each of the frame posts. The whole socket can then be easily taken apart for repairs when necessary.

Copper Production in the United States.

Census bulletin No. 96, relating to copper production in the United States, prepared by Charles Kirchhoff, special agent, under the supervision of Dr. David T. Day, has just been issued by Superintendent Porter. It contains many facts of interest and importance to the electrical fraternity.

The report shows the United States to be the largest producer of copper in the world, its product for the year 1889 being 226 055,962 pounds, or 113,028 short tons.



NEW INCANDESCENT [illegible]

The total expenditures involved in this production were $12,[illegible], of which there was paid in wages, $[illegible] 025, in salaries, $120,[illegible] to contractors, $[illegible] for materials and supplies, $1[illegible] and for [illegible] $1,112,8[illegible], the total capital invested being $[illegible] and the total employes, exclusive of [illegible] The five leading states in the production of copper are:

[illegible]

Since the tenth census reports Montana and Montana have made wonderful progress in the mining and [illegible]

[illegible] Lake Superior district, and [illegible] production. [illegible] Michigan [illegible] has been [illegible] the [illegible] pounds.

Almost all copper used for electrical purposes in the United States comes from the Lake Superior district, and the portion of the report dealing with that locality is therefore of particular interest. Following is an extract:

"From an industrial point of view the conditions under which the Lake Superior copper mining companies work are unique. The occurrence of the metal in the native state created problems for the solution of which experience in older mining regions could furnish no guide. Untrammeled by conventional methods, they have been attacked in a characteristically American manner. After an experience extending over a generation it may well be claimed that the practice of the majority of the mines is entitled to the claim of ranking with the best in this country. By systematic mining, by the liberal introduction of power drills, by the cheap handling of large quantities of rock, and by the development of crushing apparatus of great power, well adapted to the special requirements, it has become possible in the Lake Superior district to profitably extract copper from very low-grade rock.

"While the district possesses certain great advantages, it is unquestionably hampered by drawbacks. The metal exists in the rock in the native state. The ore needs only to be crushed and washed to leave behind a product called mineral, consisting of metallic copper. From the fact that the product of 117,804,926 pounds of mineral yielded 87,455,675 pounds of ingot, it follows that the average percentage of copper is 74.24. But, on the other hand, the amount of native copper in the rock is small in the majority of cases. The total amount of ore hoisted to the surface, not including the few small mines worked by tributers and one of the larger mines, was 2 363,733 short tons. This yielded 86,604,283 pounds of ingot. The average yield of the principal mines was only 1 83 per cent of ingot. Excluding, however, the two phenomenally rich mines, the Calumet and Hecla and the Tamarack, the others produced from 1,369,180 tons of rock, 27,339,536 pounds of ingot, so that the yield was .998, or almost exactly 1 per cent. of ingot copper. It follows, therefore, that a large tonnage must be hoisted to produce a moderate amount of copper. This, in turn, means very extensive underground development, and a large investment in plant and machinery for power drills, hoisting, crushing, and washing. Since the latter requires a large quantity of water, stamp mills have been located where it is most readily available and where the enormous quantity of sand can be readily disposed of. The result is that the transportation of the rock from the mine to the mill becomes an additional problem.

"These conditions impose upon the Lake Superior copper companies a conservative policy, and rob them to some extent of the ability to quickly adapt themselves to rapid fluctuations in the demand and supply. They can not at short notice respond to calls for increased product, becauses preparations for an extension of operations involve the expenditure of large sums, extended underground development, and large additions to plant and equipment, with the long time which the execution of such plans requires. They are similarly hampered in any plans for an adjustment to the conditions which an overstocked market imposes. Low costs are based in operations involving the handling of large quantities of rock upon the full employment of equipment and force. Any curtailment means an undue burden of operating expenses and fixed charges upon a diminished product, while total suspension of operations presents the alternative of either providing for a steady outlay for the maintenance of mine and plant, or ultimately, upon resumption, of paying a far larger aggregate sum as a penalty for neglect. It is natural, therefore, that consciously or not, the managers of the Lake Superior copper companies have usually followed a [illegible]

Patent Litigation over Accumulators.

Judge Coxe has handed down an important decision in the litigation over the accumulator patents, awarding a substantial victory to the Brush company by declaring in favor of the patents of Charles F. Brush. The decision was handed down July 23d in the United States Circuit Court, southern district of New York. Following is the full text of the opinion:

This is an equity action founded upon three letters patent, granted to Charles F. Brush for improvements in secondary batteries, as follows: No. 337,299, granted March 6, 1886; No. 260,654, granted July 4, 1882, and No. 260,090, granted October 17, 1882.

These patents and one other, No. 337,298, granted March 2, 1886, were before this court in Brush company vs Julien company, 41 Fed. Rep., 679. The court there decided that No. 337,298 and No. 337,299 were for the same invention, and intimated, as the inventor and his expert apparently regarded the former as the broader patent, that the difficulty might be met by a surrender of the latter or by a disclaimer of similar claims therein. This solution of the difficulty was thrown out as a suggestion merely, the final disposition of the patents being left till the settlement of the decree.

It was not the intention of the court to decide that one of these patents was entitled to preference over the other. For the reason stated and for convenience of illustration No. 337,298 was given prominence in the discussion, but the conclusion would have been the same had the position of the patents been reversed.

Upon the settlemeut of the decree the complainant selected No. 337,299 as the patent upon which it chose to rely, and withdrew No. 337,298 from the consideration of the court. This was done without objection by the defendant in that case.

On the 15th of July, 1890, after the decree in the Brush-Julien case was entered, the complainant withdrew No. 337,298 from this cause, and an order was entered dismissing the bill as to that patent. The cause has since proceeded upon the three patents as stated.

In the prior litigations involving the subject matter of these patents the following propositions have been decided:

First.—That Mr. Brush was the first in this country to hold absorptive substance, in the form of dry powder, in place on the supports of a secondary battery by paper or equivalent material, and the first who rammed or pressed it into grooves or receptacles in the plates.

Second.—That No. 337,298 and No. 337,299 are for the same invention and that the complainant was not entitled to both patents, but was entitled to one.

Third.—The complainant having elected to hold No 337,299, it was decided, by the decree, that claims numbers one, two, three, six, seven, eleven, twelve and thirteen were valid, the word "perforations" in claims numbers six and seven being construed as synonymous with "cells or cavities."

Fourth.—That the claim of No. 260,654 was not infringed by the application of the absorptive substance to the grids by a trowel or spatula.

Fifth.—That the defendants, by the use of supports filled with rows of uniform square holes, did not infringe the "rib claims" of No. 266,090.

Sixth—That claims numbers seven and fourteen of No. 266,090, the latter claim being limited to the "perforations" described, were valid and infringed.

Seventh—That No. 337,298 (and by implication No. 337,299) was not invalidated by patents Nos. 261,512 and 261 995, granted to Mr. Brush, July 18, and August 1, 1882, respectively.

Eighth.—That No. 337,298 (and by implication No. 337,299) was not invalidated by the expiration of the Brush Italian patent.[1]

All of these conclusions were reached after careful study and mature deliberation, and now, after having been re-examined in the light of the present record, arguments and briefs, except as to claims numbers eleven and thirteen of No. 337,299, are reaffirmed. No useful purpose would be subserved by again discussing them, as such a task would only involve a repetition of what has been said already in the other cases.

The proof of infringement is substantially the same as in the Brush-Julien case. It is more complete as to the manner in which the active material is applied to the plates, but in this respect it only emphasizes the former decision as to the non-infringement of the claim of No. 260,654. That claim is as follows:

> "The method of forming the plates of a secondary battery, consisting in forming receptacles for oxide of lead in its surface, then applying oxide of lead to the plate and within such receptacles and afterwards subjecting the oxide of lead to pressure."

The claim clearly contemplates not only the treatment adopted by the defendants, but afterwards subjecting the oxide to pressure. The defendants apply the oxide to the plates and within the receptacles with a wooden trowel in the hands of the workman, and there they stop. They do not subject the oxide to pressure afterwards.

The questions arising upon the expiration of the Italian patent and as to the validity of the "red lead claims" are, however, presented by this record in a new and different aspect and may, with entire propriety, be examined de novo, [illegible] with the question, not heretofore considered, relating to the effect of the Brush patents Nos. 260,653 and 276,155 upon the broad patent in suit.

It is thought that claims numbers eleven and [illegible] are void for lack of invention. The specification, after referring [illegible] mechanically applied to the plates, proceeds:

> For example the best object of lead to secure the preparation of the plates; but as this is rather expensive to prepare red lead or minium may be used."

If the record contained nothing but this statement, the claims could not be upheld. After the invention of a support primarily coated with mechanically applied oxide of lead, merely coating the plate with the commonest, cheapest and best known form of lead oxide, did not require the exercise of the inventive faculties. Especially is this so when the patentee himself asserts that the best results can be obtained by using peroxide. It would seem that the use of red lead would at once occur to any one who had even a superficial knowledge of the art. There is no more novelty in using red lead for the coatings than there is in using cast lead for the plates. (Brush v. Julien, supra, p. 682.)

The following paragraph taken from defendant's brief states with clearness and precision the views of the court upon this subject:

> "The specification says that red lead is inferior to the peroxide, and we submit that no valid claim can be founded upon the use of an inferior article when it is shown that the use of the superior article is old."

Patent No. 337,299, at least as far as its broad claims are concerned, is not invalidated by anything contained in the Brush patents No. 260,653 and No. 276,155. The application for the former (No. 260,653) was filed June 15, 1882, a year and two days after the application of No. 337,299.

No one can read the specification of No. 260,653 without being impressed with the fact that the inventor intended to confine the patent to a single point, namely, the form of the electrodes. He expressly says so:

> 'This application is a division of my application designated as 'Case I' [337,298 9] filed June 13, 1881, in which other features of my invention are claimed. For convenience in distinguishing this invention among others of mine in the class of secondary batteries I have denominated it 'Case I, Division A.'"

Again he says:

> "My invention consists essentially in a secondary battery element consisting of a structure of etagére-like form, containing in the spaces between its shelves lead in a finely divided state."

The claim is:

> "In a secondary battery, an element consisting of a structure of etagère-like form, containing in the spaces between its shelves lead in a finely divided state, substantially as set forth."

It is true that the broad invention is described, but it is equally true that it is not claimed. It was hardly possible for the patentee to describe the subsidiary invention without disclosing his main invention. Having disclosed it, had he permitted the patent to issue without warning or reservation, and after the broad invention became public property, had filed an application covering what he had thus relinquished to others, it is probable that he would have been informed, either in the patent office or in the courts, that his application came too late. But that is not this case. Before his application for the subordinate invention he had applied for the superior one. In the former he expressly informed the public that it was but a division of the latter. He could do no more. The delay in the patent office cannot be charged to him. Even though the inventor were responsible for the issue of the divisional before the principal patent—and he was not—the fact of such prior issue in no way misled the public. They never for a moment acquired the right to use the broad invention. An infringer, with the statements on the face of No. 260,653 before him, would scarcely have the hardihood to assert that he supposed the broad invention was released. No court would listen to such a plea. The claims of that patent did not protect Mr. Brush in the use of the broad invention. A person who did not use an 'etagere shaped" plate, could, if no other patent prevented, use the broad invention with perfect impunity. No. 337,299 was intended to prevent such use.

The court has not been able to discover an authority holding a broad patent invalid in such circumstances. None has been cited by counsel.

What is true of No. 260,653 is also true of No 276,155.

Mr. Brush was the first in this country to make the broad invention as stated above. He is entitled to the fruits of his invention. It is the policy of the law to reward him.

Where the court can see that the patentee has produced an invention of real merit, it should not be unduly industrious in endeavoring to discover some statement or act of his by which, on technical grounds, his rights may be forfeited. It should rather be sedulous to protect him.

Whether or not the improvements patented by Nos. 260,653 and 276,155 are the same as the improvements covered by some of the claims of Nos. 337,299 and 266,090 it is, perhaps, unnecessary to decide, for none of the claims in issue and infringed are so affected.

It seems that in his anxiety to claim his invention in every conceivable form, the patentee has involved himself in a labyrinth of descriptions and claims in which electrician and lawyer alike are quite apt to become confused.

What Mr. Brush accomplished in 1879 and 1880 can be embraced in a brief, clear and concise statement. What he actually did is the test by which his patents must be judged. He is entitled to what he invented and only this. His patents can receive no broader construction, because he described his inventions with irksome prolixity and gives to the same structure a wearisome variety of names. The nomenclaturist should not seek the reward for his labors in the patent office. A person is not entitled to a patent because he has invented a new word. The danger and impropriety of holding a number of claims relating to the same structure, and which can be differentiated only by the most abstruse and metaphysical distinctions seem

apparent. They are calculated to embarrass the inventor and mislead the public.

Did patents Nos. 337,299 and 266,090 expire with the Italian patent?

The Italian patent was applied for July 28, 1882, sealed August 8, 1882, and was issued for a term of three years from September 30, 1882. It expired September 30, 1885, never having been prolonged, renewed or extended. No. 337,299 was granted March 2, 1886, No. 266,090, October 17, 1882, both were applied for in June, 1881.

Having stipulated that the patent was issued for an unextended term, from September 30, 1882, and that the translation appearing in the record is a correct one, the complainant is not in position to argue that the patent was either extended as to time or limited as to its terms.

Especially is this so in the absence of the Italian patent law, which is not in evidence, and of all proof tending to establish either extension or limitation.

The difficulty with the complainant's argument in this regard is twofold; first, there is no law, and, second, there are no facts upon which to base it.

Section 4887 of the revised statutes is as follows:

> "No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention, which has been previously patented in a foreign country, shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years."

Under this section the test of identity between the foreign and the domestic patent, as established by the supreme court in two recent decisions, may be stated as follows:

Is the principal invention in each, is the thing patented abroad, the same in all essential particulars as the thing patented here; would the home patent be infringed by a structure made in accordance with the provisions of the foreign patent?

In cases where these questions are answered in the affirmative the United States patent falls, and it will not be saved by the fact that it contains improvements not found in the foreign patent.[1]

Whether the expiration of a foreign patent for an improvement only will operate to overthrow a domestic patent for a broad invention, which contains also a claim covering the improvement, has not apparently been decided by the Supreme Court. The language of the court in Siemens vs. Sellers, *supra*, is perhaps, comprehensive enough to cover such a contingency, but this is a question which need not now be considered.

In the Brush-Julien case the court commented upon the absence of expert testimony relating to the Italian patent. No similar observation can, with propriety, be made regarding the present record. It would indicate a lamentable want of appreciation on the part of the court to ask for additional instruction and advice. Eight experts of greater or less prominence and attainments have testified upon this subject. Three of these, called by the defendants, have expressed the opinion that the divisions of the Italian patent describe everything claimed in the United States patents granted to Mr. Brush and that the inventions covered by the two patents, No. 337,299 and No. 266,090, are literally described and substantially claimed in the Italian patent.

On the other hand five electricians, including the patentee himself, have testified that the Italian patent relates to inventions wholly different and proceeds upon totally dissimilar lines. In short, that it is but a progressive step in the Plante method, its object being to aid the process of electrical disintegration of the plates in the electrolyte, and not to supersede that process by placing the active material mechanically upon the plates prior to immersion in the battery fluid.

The mere fact that these gentlemen of conceded ability and learning, whose motive is to enlighten the court and who were all sworn to tell the truth, differ so radically regarding the meaning of the Italian patent is of itself suggestive.

The defendants plead the defense of forfeiture. They must prove it by a preponderance of evidence. And yet upon the question of the identity of the patents in question there is a sharp difference of opinion among those who are most entitled to speak upon the subject. Is there not room for the assertion that the defendants have failed to sustain the burden in this behalf?

When this question was presented in the Brush Julien case the mind of the court was in doubt, and now, having re-read the Italian patent in the light of the new testimony, it is still in doubt, but inclining more strongly to the opinion that the complainant's contention is correct. The court is not prepared to hold, therefore, that the Italian patent is for the same inventions as those covered by the two patents in question.

The principal reasons which led the court to adopt this view may be epitomized as follows:

First.—The language of the Italian patent is entirely different from that of the patent in suit. The drawings are different.

Some of the divisions of the Italian patent are unquestionably dissimilar and some concededly relate to the Plante process. The broad statement relating to the primary coating of the supports with active material is not found in the Italian patent.

Second.—The inventor's statement of his intent and purpose in taking the foreign patent and his reasons for not attempting to patent the invention of No. 337,299 abroad.

1. Siemens vs. Sellers, 123 U. S., 276; Com. Co. vs. Fairbanks Co., 135 U. S., 176.

This testimony is corroborated by his notes made at the time he was perfecting the inventions patented abroad. When these notes are placed side by side with corresponding portions of the Italian patent it will be seen that they are substantially similar. Mr. Brush testifies that the portion quoted describes the invention of Division D of the Italian patent.

[illegible] "A [illegible] very finely granulated or precipitated coal, and [illegible] superficially each particle, spontaneously [illegible] ing the metal, I will get a lead plate having minute seams throughout [illegible] with oxide of lead. [illegible] 'forming' in the battery. It will probably be found [illegible] lead on one or both sides with this peculiar fissured metal, so that the rapid oxidation in the battery will be arrested by the rolled metal when the prepared metal [illegible]

condition, pressed or united together into a coherent mass.

[illegible] lized, granulated, precipitated, or other finely divided state, and [illegible] cess or application. * * * I now [illegible] and consolidated into a compact and firmly coherent mass. The [illegible] where ramifying and extending [illegible] lead oxide within and throughout the mass greatly facilitate the penetration of the electrical action in 'forming' the plates for operative use in secondary batteries."

The notes of March, 1882, seem to describe the invention of Division D; they certainly do not describe the invention of No. 337,299.

Third.—United States patents, other than those in question, were issued to Mr. Brush for the divisions of the Italian patent, evidently including Division D. At that time, therefore, neither the inventor nor the Patent Office officials thought these inventions, or any of them were the same as No. 337,299. Furthermore, the attention of the officials was particularly called to the foreign patents.

The opinion of the United States officials seems to have been entertained also by those of Italy, France and England.

Faure's invention was well known abroad and yet the patents issued to Brush with no objection apparently, from any source that they interfered with Faure.

Fourth.—The fact that a sharp distinction is drawn in No. 337,299 between the inventor's and Plante's method. Mr. Brush claims his secondary battery element "as contradistinguished from a plate or element having the active material produced by the disintegrating action of electricity as in the well-known Plante process."

There is nothing of this in the Italian patent. On the other hand the inventor clearly intimates that the plates of Division D are to be formed by the Plante process.

Fifth.—The vast superiority of the electrodes of the United States patents in question over those made in accordance with the directions of the Italian patent, as demonstrated by the experiments of the complainant's experts.

A careful reading of Division D in the light of the testimony has convinced the court that some, at least, of these experimental plates are made in conformity with the formula of that division. None of them are like the plates of No. 337,299.

Sixth.—The Italian patent is capable of a narrow construction which differentiates it from the patents in suit.

When to the statements of the patent itself is added the testimony of the inventor that he intended to limit the patent in all its branches to a coating formed by the action of the electric current and that he did not intend it to cover a coating placed on the plates mechanically before they are subjected to electrical action, there seems to be every reason why the narrower construction should be adopted.

Seventh.—The fact that the element of the Italian patent is produced by heavy pressure, hydraulic or otherwise, whereby the particles of lead and lead oxide are compacted into a firmly coherent mass having minute veins of oxide of lead everwhere ramifying through it.

There is nothing resembling this in the United States patents in suit.

Eighth.—The "mass" described in the Italian patent is malleable and capable of being made into strips or wires and manipulated so as to form any style of element.

Neitheir the active material of No. 337,299 nor the completed plate of that patent is capable of such treatment.

Ninth.—No. 337,299 is designed to cover Mr. Brush's inventions made in the summer of 1879 and in the summer and autumn of 1880.[1]

Bearing this in mind, it is quite clear that the discoveries of these years alone are insufficient to support the Italian patent. Something more is required. What Mr. Brush did in 1879 and 1880 is not described in the Italian patent. What he did in 1882 is described there.

The foregoing are some of the reasons which have induced the court to overrule the defense of forfeiture; in fact, the more the Italian patent is studied the more settled becomes the conviction that it is not for the same invention as No. 337,299.

Apply the test suggested in Commercial Manufacturing company vs. Fairbanks company, 135 U. S., 176, 194. If a person in this country, after the issue of No. 337,299, were to commence the manufacture of secondary batteries by the precise processes described in the Italian patent,

1. Brush vs. Julien, *supra*, 187; Accumulator vs. Julien, *supra*, 129-131.

[illegible] ing the writ.

[illegible] statute creates it, and in all cases where the facts are clear the statute must be implicitly followed. But no one can examine the course of judicial decision upon the subject [illegible] sought to construe it liberally, and have seldom, except in the plainest cases, permitted it to defeat a valuable patent. [illegible] protection for a meritorious invention, the court should not, unless fully convinced that the facts warrant such a course, destroy his patents upon grounds which do not go to the merits of the invention, and which, for want of a more accurate word, may be termed *technical*.

[illegible] public should [illegible] to protect them abroad is, on principle, not easy to comprehend.

It is said that the expiration of the Italian patent threw the invention into public domain. So it did into the domain of the Italian public, but if Mr. Brush had taken no patent in Italy the Italian public could have practiced the invention from the moment it became known there. Had he taken no foreign patents his invention would have been thrown into the public domain of every land but this. In this country his inventions would have been protected for seventeen years; outside of this country they could have been used with perfect impunity. The inventor applied for his patent here long before he applied abroad, but through the delay of the patent office the foreign patents were issued first.

Assuming the inventions to be similar, the inventor has been guilty of no fault, the American public has lost no rights, and yet, under the provisions of this statute, which it is thought was never intended to apply to a case like this, a valuable monopoly is destroyed.

These observations are, perhaps, only germane to the present inquiry as they tend to emphasize the suggestion already made that in dealing with a defense where, as in this case, the disaster following the inventor's acts is so out of proportion with the fault, if fault it be, the court should proceed with the utmost caution, and, where the evidence is not clear, give to the inventor the benefit of the doubt. If convinced that he did not intend to patent the invention abroad, the court should not by construction broaden the language of the foreign patent so as to destroy the domestic patent, when that language is capable of a construction which permits the domestic patent to live.

The question of how to dispose of No. 337,298 is, in view of complainant's position regarding it, more puzzling than ever. The rule which obtains in this Circuit, requiring a disclaimer of invalid claims as a condition of a decree, has always seemed an arbitrary one. It certainly seems inequitable that the court, at *nisi prius*, should compel the patentee to renounce forever a claim which may be held valid upon appeal. It is possible that this rule may be modified by the Circuit Court of Appeals.

In view of this contingency and of the extraordinary and distinguishing circumstances surrounding this case the court has concluded, if the complainant upon reflection still desires to assume the responsibility of retaining two patents for the same invention, not to require a surrender or disclaimer of No. 337,298 as a condition of a decree. It is thought, however, that pending an appeal it should be deposited with the clerk to await the further order of the court.

An accounting having been waived, it follows that on filing a disclaimer of claims eleven and thirteen of patent No. 337,299, the complainant is entitled to a decree upon claims one, two, three, six, seven and twelve of this patent, and upon claims seven and fourteen of No. 266,090, for an injunction, but without costs.

CORRESPONDENCE.

New York Notes.

NEW YORK, July 25.—[illegible] State Naval Militia have been the heroes of the week in New York. As I wrote you last week the squadron of evolution has been anchored in the Hudson river, right off the western edge of New York city. Several preliminary drills have been organized for the benefit of the militia, and on each occasion the spectacle has been highly appreciated by tens of thousands of citizens who have crowded the docks and pier and all the river craft available for sight-seeing purposes. On Thursday night a [illegible] "distant service" was held, and at the same time the vessels of the squadron gave a magnificent [illegible] valuable services rendered by the electric projectors, the use of the Ardois system of [illegible] thrown in as a sort of side show. [illegible] has four search lights placed one at each [illegible] ward and after bridges. The projectors are Mangin arc lights of 25,000 candle power each, [illegible] amperes at 50 volts. The projectors [illegible] cruisers were in service at the same time, shafts of light now sweeping the banks of the river, then cast upward so as to form great [illegible] concentrated on a single vessel or portion of the squa[illegible]

formed a spectacle that was quite unique and fairly bewildered and delighted the crowds that occupied every available inch of space ashore and afloat from which the gigantic pyrotechnical display could be seen. The Ardois system of electric light signalling was used for communicating orders throughout the manœuvres. Ten incandescent lamps are strung in two vertical rows from the mizzen-top-mast head, the lamps being a considerable space apart to facilitate distinguishing the combinations from a distance. The lamps of one row show a red light and those of the others a white light. Only five lamps are lighted for each signal, the signals being made up to combinations of reds and whites. Five whites or five reds can be shown at once, or two reds and three whites, or one red and five whites, and so on in any combination of five, the total number of combinations possible being 62. The working of the lights is controlled by a circular switchboard provided with a revolving and depressing switch lever and connected with an automatic circuit closer. The signals are made instantaneously by turning the lever to the particular segment required among the 62 divisions of the switch and then depressing it; the proper lamp connections are then made automatically by the other devices of the system. This night drill, whatever it did to get the naval militia into training, certainly afforded a convincing demonstration of the value of the electric light in naval warfare. To-morrow the militia will leave for Fisher's Island, where their week's hard work will begin on Monday. Curiously enough, in spite of the very general interest shown in the proceedings, only $1,700 of the $5,000 needed for the expenses of the drill has yet been subscribed.

The rapid transit question is being discussed with a good deal of vigor just now. This week the commissioners screwed their courage up to the point of making public the route and style of road they have decided on for the east side of the city. It is to be a four-track underground line diverging from the proposed Broadway line at Fourteenth street; that is, nearly three miles from the down town terminus of the line, which was originally intended to serve the west side only. About two miles of the upper portion of the line is to be on a viaduct built over private property. The surveys, plans and specifications are left to the engineers, who are directed to have them ready "at the earliest practicable date." The road is to be operated by electricity or some other power not requiring combustion within the tunnel. It is not proposed to lay out a third line east of the one just decided on; the commissioners apparently intend to wait and see if capitalists will have the courage to face the situation. That the commissioners have their doubts on this score is pretty evident from the way they express themselves publicly, but unofficially. One of them says that "the commission has given to the public its best idea as to how rapid transit for New York should be realized. Capitalists must decide for themselves whether or not there is money in the project." The thing is that the "best idea" of the commission has been so overlaid with poor ideas that it is very doubtful whether capitalists will be tempted to put money into the project. The original idea of an electric underground road, or rather two roads, one for each side of the city, was excellent, certainly the best idea the commission has had. If capitalists had been allowed to work on that idea and build the road according to the best system obtainable the franchise would probably have been in great demand. The plan now given out of having the east side route branch off from the line from the west side at a point about two miles above the center of the business district is a fatal mistake. Anybody with an atom of common sense who has seen the evening and morning jams on the four elevated roads during the busy hours must see in a moment that it would be impossible to properly handle the traffic if the trains of both [illegible] have to run over a common track [illegible] of the city. Such a scheme is [illegible] if it were intended merely [illegible] a system intended to permanently solve the difficulty of rapid transit in New York it [illegible] has put aside the simple and economical Greathead system of tunnel[illegible] to deep [illegible] near the surface as [illegible] the commission are [illegible] two [illegible] of the [illegible] The [illegible] of the [illegible] system [illegible] the [illegible] [illegible] [illegible]

Street Railway company asking that the former be enjoined from stringing new wires where the latter's wires are now, or from using these wires, was overruled. The temporary injunction was also made perpetual, and all that the Consolidated can now do is to appeal. This will prevent the Consolidated company from changing some of its horse car lines to electricity for some time

The latest move in the litigation between the two companies comes from the camp of the Consolidated people, and is in the nature of a petition in quo warranto proceedings brought in the name of the attorney general of the state. The claim is set up that the Toledo Electric Street Railroad company has abused its corporate authority. The company was organized April 11, 1890, and the legislature gave it authority to appropriate property necessary for the use of existing street railway track for not more than one-eighth of the entire distance between the termini of the route as actually constructed. The attorney-general claims that this act is unconstitutional on the grounds that it conflicts with section 26, article 2, in that it relates to the exercise of the sovereign power of eminent domain, is general, and does not have uniform operation throughout the state; that it conflicts with section 1, article 2, in that it purports to confer by special act the power of appropriating; that it is a special act conferring corporate powers; that it conflicts with section 19, article 1, in that it authorizes the appropriation of property already devoted to and in public use for street railway purposes to the use of another corporation for the same public purpose. The questions involved are similar to those in the case of the Cleveland roads, affecting the change from horse to electric power.

The Postal Telegraph, Consolidated Street Railroad, Toledo Electric and Western Electric companies of Toledo have joined in erecting a new line of poles on Superior street. Some of the poles are sixty and seventy feet high.

Pittsburg, Pa.

PITTSBURG, July 25.—The Braddock & Turtle Creek Electric Railway company has now commenced operations. The line was finished last week, and on Sunday, the opening day, the capacity of the road was fully tested. Three cars carried 4,000 passengers. The people of Braddock have for a long time been clamoring for a rapid transit railroad and the electric system meets with general approval. The line is now a little over two miles long, but the company is already contemplating an extension, and when the entire road is completed the company will operate about five miles.

Another progressive step toward the removal of the overhead wires in large cities took place yesterday by the organization of the Pittsburg Underground Electric Construction company, to equip electric and cable street railways with the underground systems under the patents of John J. Miller of this city. The gentlemen composing this organization are cautious and conservative, and it is believed the project is a good one, and from the position the gentlemen hold in the business world the combination is of great financial strength.

The officers and directors elected were C. D. Robbins, a successful oil producer of Washington county, as president, and D. J. Rex, manufacturer, as secretary and treasurer. C. F. Shoemaker, superintendent of Liggett Spring and Axle company, F. A. Mann, nut and bolt manufacturer of Cleveland, O.; F. J. Osterling, architect, and John J. Miller of the Robbins Electric company, the inventor of the system, comprise the directory. The company is organized with a capital stock of $300,000, of which $96,000 was paid in yesterday.

The inventions consist of a complete system of street railway appliances, motors, underground trolley, rail and road bed.

Sterling, Ill.

STERLING, July 25.—About two years ago the Union Street Railroad company obtained a franchise for a road in Sterling and Rock Falls and at once commenced construction. The Sprague company constructed about six miles of trolley wire and feeders; car barns were built and a power house added. Work was then discontinued, and the time allowed in the franchise expired. Last Monday evening Charles D. Jameson of Iowa City, Ia., applied for a franchise over the right of way of the Union company and agreed to file bonds to carry out the work. It being necessary to advertise the application for ten days, and form a stock company; the matter will be again brought up Monday evening, Aug. 3, when it is probable the franchise asked for will be granted.

The Sterling Gas and Electric Light company has commenced work on the head race tunnel which, when completed will be three times the present dimensions.

B. W. F.

PERSONAL.

Egbert G. Handy, president of the Columbia Electric company, St. Paul, has been in Boston and New York for the past three weeks.

J. H. Stahley, formerly with the North American Construction company is now in charge of the construction department of Kohler Bros. & Grier.

G. A. Edward Kohler, of Kohler Bros. & Grier, has just returned from an extended business trip through the east, visiting Philadelphia, New York and Boston.

C. A. Daigh, manager of the Electric Engineering & Supply company, St. Paul, has been in Chicago the last week getting the fine new office in order that has recently been opened by his company in the Rookery. The St. Paul office is managed by Morgan Brooks, the company's treasurer.

Dr. D. C. Jackson of Madison, it is reported, has been tendered the professorship of electrical engineering at the state university of Wisconsin. At present he holds the position of electrical engineer of the Consolidated Edison company of Madison, Wis. It is thought that he will accept the appointment.

W. J. Heald has been appointed superintendent of the operating department of the Minneapolis electric street railway system. Until recently Mr. Heald has had charge of the work connected with the overhead construction for the same company, the appointment coming in the line of promotion. Mr. Heald is a young man but he has won his spurs in active service and his appointment meets with approval in the Flour City.

C. C. Smith of the firm of Carr & Smith, electrical engineers, Minneapolis, has been engaged by the Villard company to take charge of the practical work connected with the rebuilding of the Milwaukee street railway system under Chief Engineer Julius Myers. Mr. Smith has been with the Minneapolis company nearly two years, having had entire charge of the installation of its magnificent plant, after plans and specifications prepared by Mr. Carr. As a reward for meritorious work he has been sent to Milwaukee, where his position will entail greater responsibilities.

NEW INCORPORATIONS.

Carpenter Electric Light & Motor company, Washington, D. C.; capital stock, $100,000; dealing generally in all kinds of electrical appliances

Merchants' Electric Light company. Leavensworth, Kan., capital stock, $50,000; to manufacture and supply light to the public by means of electricity.

Wisconsin Gas company, Chicago, Ill.; capital stock, $2,000,000; to build and operate gas and electric plants for all purposes to which the use of same may be adapted.

Cutter Electrical and Manufacturing company, Camden, N. J.; capital stock, $100,000; to manufacture chemical, electrical and mechanical devices, novelties and appliances.

Beatrice Light & Power company, Beatrice, Neb.; capital stock $250 000; to construct and maintain gas and electric light works for light, heat, power, etc., in Beatrice and other places.

Harvey Transit company, Chicago, Ill.; capital stock, $150,000; to construct a railroad in Harvey, Ill., and contiguous territory to be operated by animal, steam, electric or other power.

Youngstown Street Railway company, Youngstown, O.; capital stock, $500,000; building and operating street railroads to be operated by horses cable, electric or other power, and to furnish power and light, etc.

Light, Heat & Power company, New Albany, Ind.; capital stock, $50,000; to purchase, establish, erect and maintain an electric light station with all proper attachments for the purpose of furnishing electric light, heat and power to all persons desiring to use the same in Floyd and Clark counties, Ind.

United States Bulletin company (incorporated in West Virginia), New York, N. Y.; capital stock, $200,000; manufacturing, selling and renting, using or licensing electrical and mechanical bulletins, appliances or apparatus to report base ball games, and other amusements, sporting or public events.

ELECTRIC LIGHT.

The people of Leroy, Fla., are talking of introducing electric lights.

The erection of an electric lighting plant in St. Bernard, La., is talked of.

It is reported that an electric light plant will be erected at Riverside, Texas.

The Tampa, Fla., Illuminating company will, it is stated, change its incandescent plant to an arc light system.

It is reported that the big Alcazar hotel in St. Augustine, Fla., will be fitted with a new electric light plant.

At a recent meeting of the city council of High Point, N. C., E. A. Snow and J. E. Cox were appointed a committee to purchase an electric light plant for the city.

A paper on "Incandescent Electric Lighting" was recently read before the Illinois Chapter of the American Institute of Architects by Thomas G. Grier of Chicago.

The Edison Electric Illuminating company of Rochester, N. Y., has taken possession of its new property. The site cost $91,000. The company has issued bonds aggregating $300,000.

[illegible] Duluth high school for 581 incandescent lights. The company is [illegible] plant at Anderson [illegible] some time since.

The Edison Electric Illuminating company of Brooklyn, N. Y., has [illegible] ing station at [illegible] feet front and [illegible] deep. [illegible] teen No. 32 dynamos, [illegible] horse power Ball compound engines

ELECTRIC RAILWAYS.

An electric road from Chattanooga [illegible] Park is contemplated.

At Norfolk, Va., the Norfolk & Atlantic Terminal company intends building an electric line.

The St. Catherines, Ont., electric street railway, owing to financial embarrassment, has passed under the control of the Bank of Toronto.

The San Antonio, Tex., Rapid Transit Street Railroad company has contracted with the Thomson-Houston Electric company for the equipment of its electrical railroad.

Twenty new cars have just been added to the rolling stock of the Minneapolis Street Railway company. They are from the shops of the Northern Car company of Minneapolis and are highly commended.

Work on the electric railway at New Westminster, B. C., is steadily progressing. The foundations of the power house are finished and the work of its completion and fitting up will go forward without delay.

A new electric street railway company has been incorporated in Columbus, O. It will be operated in the extreme northeastern and northwestern sections of the city named and will also extend to Green Lawn cemetery.

The Galveston City Railroad company of Galveston, Tex., has let the contract to Noah Hamlet and W. D. Holtzman at $50,000 for the erection of its electric power house. The building will be 99x280 feet in size, and four stories high.

S. D. Loring, representing bondholders, has purchased the Houston, Tex., street railway property of the Fort Worth Land & Railway company. The property includes 10 miles of street railway, electric plant and equipment and real estate. The purchasers will, it is stated, make a number of improvements.

An application has been made to the Jamaica, N. Y., town board by the Brooklyn City Railroad company for permission to extend its Myrtle avenue line to Richmond Hill. Many property holders along the proposed extension were present at the meeting. They all favored the proposed extension. President Lewis of the railroad company said that the company intended to operate the whole road eventually by electricity. The next hearing will be on Sept. 14th.

ELECTRIC MOTOR.

Floyd, Gallagher & Co. have organized the Edison Electric Power company at Meridian, Miss., and are, it is tated, erecting an electric power plant.

The *Chicago Herald* is authority for the following item: "A queer suit in equity has been brought against a Philadelphia dentist. He has on his premises an electric plant with which he pulls teeth. The engine, dynamo and machinery make too much noise for the neighbors, and they have petitioned the court to have the nuisance abated."

TELEPHONE.

The telephone line between the German cities of Munich and Stuttgart, 125 miles in length, was started working on July 1st. Twenty-four cents is charged for five minutes' conversation.

The *Manufacturer's Record* is authority for the statement that the South Florida Telephone company will erect a factory for the manufacture of C. J. Seeger's patent telephone instrument at Bartow, Fla.

MISCELLANEOUS.

One of the best schools of electrical engineering in the country is that connected with Columbia college, New York, and at which Prof. F. B. Crocker is instructor. Full information regarding it is given in the recent [illegible] "circular" issued by the School of Mines of that institution.

O. W. McKinney of Rochester, N. Y., writes to the New York *Sun* to cite the case of John [illegible] Mass., who is alleged to have received a current [illegible] volts for over a minute with no more dangerous injuries than severe burns on his left hand and a large [illegible] left side, extending from shoulder to toe.

A beneficent product of ingenuity in [illegible] tion is an invalid chair which can be [illegible] ease that an attendant can be dispense[illegible] valid can, if desired, take his constitutional [illegible] eight miles on hour. Underneath the chair are placed the motor and the storage cells, and the guiding apparatus and that for controlling the motor are conveniently arranged. At a moderate speed he [illegible] miles of travel.

ELECTRIC MINING.

[illegible] the Hulls Mining company of Neihart, [illegible] a contract to the Thomson-Houston Electric company for a complete mining plant. C. L. Parker superintendent of the works, says: "This plant will be the first complete electrical machinery equipment and the [illegible] It will consist of electrical pumps, drills and hoists The hoists are for use in a 2,000-foot shaft, but for the present will only be used 1,000 feet. The machinery will be completed and ready for shipment as soon as the railroad is finished to Neihart, which will be in about sixty days, and inside of ninety days will be in operation. The drills can be operated in any part of the mine—three will be operated at once and within six months, or, as development goes on, six will be in use. The introduction of this electrical machinery will work a revolution in the manner of taking ores from the ground and its operation is being watched with interest all over the state; and when the electricity is once applied, there will be hundreds of mining men present to watch it, for upon the success of the plant hangs the fate of the application of electricity to working other mines in the Neihart district. The new process, it is claimed, simplifies mining and reduces mining operations to the minimum of cost."

TRADE NEWS.

[illegible] H. Bennett & Co., New York, have begun an action against the Manhattan Electric Supply company for alleged infringement of patent on the Burmley dry battery.

The Great Western Electric Supply company at a meeting of its directors, July 1st, declared a 2 per cent. quarterly dividend on $350,000 of preferred stock. It is announced that the company will soon pay 6 per cent. on common stock.

At the fourth annual exhibition of the Amateur Photographer's society of New York the Clark Electric company was awarded a silver medal of excellence for its arc lamp for electric optical lantern apparatus. This is the first and highest medal ever issued by the society for electric light for optical purposes in photography.

Hewlings' Directory of Steam Specialties and Engineering Appliances is out. It contains classified lists, with an index, of the names of manufacturers of the articles mentioned in the title. The compilation will undoubtedly prove of value to users of machinery of this class. A. J. Hewlings, 218 Lake street, Chicago, is the publisher.

The Electric Merchandise company reports large sales of the Pratt portable register for street car use. The company claims that this device is superior in many ways to other standard makes. Large orders have already been filled, and claims made by the company seem to be supported by the experience of those who have adopted the device.

"The Transmission of Electric Power" is the title of a handsome pamphlet just issued by the C. & C. Electric Motor company, New York. Besides a brief general article on the subject the little book contains the rates charged for electric power in many cities, forms of contracts for power and an essay on "A Proper Basis for Determining Electric Motor Rates."

The Pond Engineering company reports encouraging business from the Southwest. It is building the complete power plant for an Edison central station at El Paso, Tex.; also a complete plant at Paris, Tex., for lighting and railway service. The company is furnishing Armington & Sims engines for Texarkana, Ark., and Austin, [illegible] for the new capitol building the second engine of this make now in the capitol.

[illegible] Lamp company, 203 S. Canal street, Chicago, Ill., has greatly enlarged its manufacturing facilities, and is now prepared to fill all orders for the Sun arc lamp promptly, either for incandescent or arc circuits. The Great Western Electric Supply company has secured the general agency for the west; this lamp has been upon the [illegible] and it has received a phenomenal success, especially among the isolated plants and central stations that have the direct incandescent system. This [illegible] gives a bright, steady, white [illegible] also engage extensively in the manufacture and introduction of several new articles, upon [illegible]

BUSINESS.

[illegible] are issuing a circular describing the boilers they are installing for electric light [illegible] a number of stirring [illegible] three city [illegible] [illegible] [illegible]

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 20, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and **is guaranteed to be waterproof, and will not deteriorate, oxidize or crack,** and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

"What time is it?"

Who can tell?

The mechanism is all right; the Clock ticks, the wheels go round with their accustomed regularity—but to what purpose? There is not much lacking, only the Hands gone.

The Central Station is all right; the wheels spin around with cheerful humming. The Dynamo sings a busy song; the Fuel burns with a gleeful sputter; the trembling Meters tell of outgoing Energy.

"Going where?"

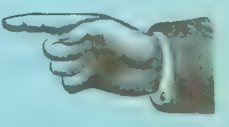
It will go down your poles, into trees, over awnings, along crossed lines, wherever it wills, a Fugitive Force, unless the Insulation is there.

Do you use Shield Brand Wire?

A NEW BOOK!

NOW READY.

ELECTRIC TRANSMISSION HAND-BOOK.



Lieut. F. B. Badt's latest addition to our famous hand-book series, of which 20,000 copies have been sold. The new book deals in the author's well-known practical style with all the problems of Electric Power Transmission.

THE BUTLER HARD RUBBER CO.,

33 Mercer Street, New York,

POSSESS SUPERIOR ADVANTAGES IN THE MANUFACTURE OF

HARD RUBBER GOODS

Especially in articles adapted to electrical industries, having obtained the sole right to manufacture HARD RUBBER under the valuable Patents granted to WILLIAM KIEL.

ALL OPERATIONS OF SAWING, CUTTING, TURNING AND POLISHING OUR NEW STANDARDS OF

SHEET, ROD AND TUBING Can be performed with a large reduction in the wear and tear of tools, and considerable saving of labor. Our new standards are of a richer black throughout, not subject to change in color, are tougher and more flexible, do not become brittle with age, and have been tested and approved by the leading electrical companies of the United States. In addition to these advantages, we also offer advantages in prices.

KIEL'S PATENT HARD RUBBER CELLS FOR STORAGE AND PRIMARY BATTERIES

Still remain the most satisfactory and cheapest in the market, unequaled for strength, durability, insulation and resistance to acids.

HARD RUBBER GOODS OF EVERY DESCRIPTION MANUFACTURED.

Correspondence solicited from all manufacturers and dealers in electrical machinery and supplies. SEND FOR PRICES AND ESTIMATES.

Vol. IX. CHICAGO, AUGUST 8, 1891. No. 6

Charles D. Shain.

Few men now in the electric lighting business are more deservedly popular than the subject of this sketch. Energetic and pushing, yet withal most courteous in his treatment of those with whom he is thrown in contact, Charles D. Shain has won alike the esteem not only of his business associates, but also of the large staff of employes under his personal direction.

Mr. Shain was among the pioneer representatives in the electric lighting business, and has traveled most extensively throughout the United States. A history of his varied business and engineering experiences shows him to be well fitted for his present responsible position. Like the most successful workers in the field, Mr Shain is a young man. Born in Philadelphia Nov. 8, 1855, he is therefore but 36 years of age. His school days were spent in Philadelphia. In 1872 he was graduated from the Central high school and commenced his business life as assistant to H. P. M. Birkenbine, the hydraulic engineer. While filling this position Mr. Shain was engaged on the surveys for the waterworks in Harrisburg, Lebanon, Bethlehem and other Pennsylvania towns. He was afterward employed on the engineer corps of the Johnstown & Somerset railroad. In 1873 he was appointed assistant engineer in charge of the construction on the Jefferson division of the Texas & Pacific railroad. The company, however, became financially embarrassed and the young engineer concluded to embark in a commercial venture. Accordingly he organized a party and equipped the members with an outfit for trapping, and engaged in trading with the Indians. His expedition started out early in the fall, but returned in the spring. It was not a success, and, aside from the many hardships and mishaps which befell the party, it was a failure financially, and the promotors were left in an unenviable position.

From the far West Mr. Shain drifted to Galveston and thence to Havana. He was in Cuba at the time when the United States fleet was off Havana awaiting developments in the Cuban troubles. In the spring of 1874 he returned to Philadelphia, where he engaged in engineering work on the Centennial buildings. When this contract was nearing completion he again decided to try his luck in a commercial enterprise, and accordingly returned to Philadelphia. This time he engaged in the brokerage business. The second venture was successful, but in 1880 his love for engineering led him to sever his mercantile connection and accept a position as superintendent of a New York mining company, in which he was largely interested. His mining work led him into California and Arizona, but mining in those days, on account of the restlessness of the Indians, the high price of labor, fuel, etc., was by no means an alluring occupation. So, when the position of assistant engineer on the Toledo, Cincinnati & St. Louis railroad was tendered him, it was accepted, and he then located in St. Louis. After holding the position of chief engineer of the Burlington & Ohio River railroad, Mr. Shain went to Chicago and commenced his work as a pioneer in the business with which he has since been so prominently identified.

The majority of the readers of the WESTERN ELECTRICIAN are familiar with Mr. Shain's rapid advancement since his coming to Chicago. He entered the field with the old United States Electric Lighting company at the time that concern opened its Chicago office, and filled various positions with the company until he was finally made assistant to the Western manager. At the time of the lease of the United States company by the westinghouse people, the latter company showed its appreciation of his ability by making Mr. Shain its general district agent. But he had hardly settled in Cincinnati as the representative of the Westinghouse interests, when a favorable offer was received by him from the Edison people, and Mr. Shain then associated himself with H. Ward Leonard, general manager of the United Edison Manufacturing company, with headquarters in New York. Another promotion followed shortly, and at the present time Mr. Shain is eastern district manager of the Edison General Electric company, having been appointed to that position by Second Vice-president Samuel Insull.

Mr. Shain is prominently identified with the New York Electric club, being one of its board of managers.

CHARLES D. SHAIN.

Tapping Telegraph Wires in Chicago Conduits.

It is charged that the bucket shop men of Chicago obtain the board of trade quotations by tapping the telegraph lines laid in the conduits. C. H. Wilmerding, president of the Conduit company and secretary of the Chicago Arc Light & Power company, has been interviewed on the subject. "Our franchise does not permit us to refuse to lease our wires to any one," said he. "We only ask whether applicants need them for telegraph or telephone purposes, and there our inquiry as to the nature of their business ends. I know there are several bucket shop men who use our wires, but we cannot stop them unless they are doing something illegal, such as tapping wires in order to get the quotations. As soon as we find out that anything of that kind is being done we shall dissolve the contracts. Our price is high, solely to keep bucket shop men out, but they do not seem to stop at money and they pay us for our wires."

New Use for Electric Light.

The utility of the electric light is demonstrated in a new phase, the ingenuity of which is apparent to those who patronize the cable routes through the North or West Side tunnels, Chicago. Passengers on the cars as they whirl past the whitewashed walls are suddenly startled at the sight of distinctly shadowed letters. If one looks carefully about, he may see suspended from [illegible] wire placed [illegible] such a position that the glare from the electric light will throw into bold relief on the side wall a much enlarged but perfectly distinct shadow of the advertisement. As bill-posting is not allowed in the tunnels this new device enables the far sighted merchants to advertise on the forbidden walls and yet obey the letter of the law; although it is an open question whether or not a shadow may be said to be posted.

Old Time Telegraphers.

The eleventh annual reunion of the old time telegraphers will be held at Washington Wednesday, Aug. 19th. It promises to be of unusual interest. Many notable guests will be present, including Mrs. Roswell Smith, wife of the president of the *Century* company. When Prof. Morse was endeavoring to secure an appropriation from congress for the establishment of a telegraph system, Mrs. Smith, then Annie G. Ellsworth, a daughter of the commissioner of patents, was an enthusiastic advocate of the professor's claims. It was she who first announced to Morse the fact that the bill in which he was so greatly interested had been passed by the senate. On receiving the news Prof. Morse promised his informant that she would have the honor of sending the first message over the new line from Washington to Baltimore. When the time arrived Miss Ellsworth was summoned and invited to indite a message for transmission. She immediately wrote the words: "What has God wrought?" When it was transmitted the strip of paper on which it was written was claimed by Governor Seymour of Connecticut in honor of the lady, who was a native of that state, and as Prof. Morse was educated there.

There will be many others in attendance whose recollections of the first days of telegraphy in this country will add much to the interest of the occasion.

The United States Military Telegraph corps will hold its convention at the same time as the "Old Timers." The organization embraces those who comprised the United States Telegraph corps during the late war.

At the conclusion of the business meetings of the organizations the members join hands and celebrate the remaining festivities conjointly, since many of the members of the one organization belong also to the other.

George C. Maynard of Washington, D. C., is the president of the "Old Timers," Col. W. R. Plum of Chicago is the president of the Military society, and J. E. Pettit of the Postal Telegraph company, well known to many Chicagoans, is its secretary and treasurer. Mr. Pettit is a member of both organizations, and, together with Col. Plum, founded the Military society

Following is the programme as at present organized:

August 19th, [illegible]—Business meeting of Old Timers' telegraphers' association.

August 19th, [illegible]—Business meeting of United States Military Telegraph corps.

August 20th, [illegible] societies, opportunity will be given [illegible] Capitol, Museums, Mount Vernon [illegible] interest.

The American Association for the Advancement of Science will meet in Washington on the same day that the societies meet. Many prominent men who are connected with telegraphy belong to the American association, and their presence will add to the interest of the occasion. In connection with the reunion there will be a loan exhibit of historical telegraph [illegible] articles are to be sent [illegible] properly labeled, to Geo. C. Maynard, 1309 New York avenue, Washington, D. C. [illegible] before the meeting. The National Museum has offered to

provide space and cases in the electrical section for this exhibit, and it promises to be an important feature of the occasion.

Electrical Signaling on Board the Chicago in New York Harbor.

The White Squadron made a hit as far as New York is concerned. The metropolis has been agog over the manœuvers of the cruisers. The daily papers devoted columns of space to descriptions and diagrams innumerable relating to the evolutions of the vessels. But the electric search light drill brought the growing enthusiasm to its height. Whether the interest was directly due to the mention of the magic word electric, ever so fascinating and attractive to the curious, or whether it was that the New Yorker's mid-summer evening hangs heavily, is hard to say. In any event the display on the North River was one which the New York dailies asserted to be the sight of a lifetime.

The drill took place on Thursday evening, July 23d. The squadron was anchored so that a good view of the spectacle could be had from the New York shore between Twenty-sixth and Fortieth streets. The night was cloudy, but in spite of the threatening aspect of the heavens, thousands crowded the houses along shore, and the docks and vessels, not to mention the more favored observers who found desirable points of view on board the innumerable small craft out in the stream. One New York daily went so far as to estimate the number of spectators who witnessed the electric signaling, as being more "than there are people in the state of Montana." The signal to commence the exercises was given from the Chicago at 9 o'clock and the display was over at 10:15.

FIG. 1. ELECTRIC SIGNALING ON BOARD THE CHICAGO IN NEW YORK HARBOR.

As has already been stated, numerous accounts of the proceeding have appeared. But, to the electrical man, interested more particularly in the apparatus with which the signaling was carried on, the vivid descriptions which must of necessity accompany such startling head lines as "Flashes of Fire Shoot from the Cruisers" can but be more or less unsatisfactory. With the object, then, of giving the readers of the WESTERN ELECTRICIAN a glimpse of the Chicago's electrical equipment as it appears to the visitor on board the ship, a representative of this journal, through the courtesy of Captain J. W. Miller and Lieutenant Sperry, secured the accompanying views.

Figs. 1 and 2 show the Chicago's search light and the [illegible] in the Ardois electric system of night [illegible]. Fig. 2 is taking in the Ardois apparatus [illegible]. The Ardois operating stand, or keyboard, and the five lanterns hung in the rigging, through which [illegible] may be clearly distinguished [illegible]. Fig. 3 shows the interior of the conning [illegible], the wheel house [illegible]. [illegible] get an idea as to the arrangement [illegible] each gun after the primer has [illegible] for firing. In this view it [illegible] Cape. Mounted [illegible] Mangin projectors made by Sautter, Lemonnier & Co. of Paris. The carbon holders in this instrument are set at an angle of forty-five degrees so that a better distribution of the light from the crater in the carbon may be obtained on the reflector behind. The lamp is fed by hand. The Mangin projector consists of a concavo-convex lens, the convex surface being the one of greater radius. The latter surface is silvered. The radii of curvature of the faces are so calculated that the two refractions at the concave surface destroy almost all aberration. It is claimed that this gain counteracts the loss by reflection. The beam has a divergence of but two degrees. The weight of the sixty centimeter search light complete is 1,301 pounds. The light is said to equal that of 23,000 candles.

The dynamos furnishing current to the search lights are located in a small room on the berth deck. They are on the same bed plate with the engine driving them. These machines are series wound Gramme dynamos. A glance at Figs. 1 and 2 will help the reader to understand the Ardois method of night signaling with lanterns. In this system five lanterns are employed. These are hung in the rigging, as shown in Fig. 2, and in each one there are two incandescent lamps which can be controlled from the operating stand on the bridge. One lamp in each lantern is behind a red globe, and the other is covered only by plain white glass. By this construction any lantern may be made to show either red or white. The leads from these signal lamps unite into one cable, and connect with the operating box on the bridge. In the controlling box on the bridge, Fig. 1, there is a circular plate carrying contacts, and marked with little dots of paint to indicate the combination of colored lights constituting a given signal. By moving around a needle or pointer which is pivoted on the center of the dial to the code word desired, and turning on the current, the proper combination of lights appears in the rigging. The following will give the reader an idea as to the combinations employed in the message which was spelled out after the recent search light drill. The lanterns were read from the bottom to the top:

T	Red	Red	White	White.

It is understood that the display of this system in New York harbor was the first to be made public in this country. The Ardois system has been in service, however, on the White Squadron since last January.

The gun firing system in use on the Chicago has also a number of interesting features. In the conning tower, Fig. 3, there are sighting vanes which enable the captain to determine when the enemy's vessel is on a given bearing. Each gun, through these vanes, is laid at a proper angle of train so that the fire will be concentrated. Referring again to Figs. 3 and 4, the operation of this system, which is simplicity itself, will be understood. At the gun there is the double conductor cable fitted at one end with a primer connection, Fig. 6, and the other end terminating at a socket in the deck above. In this cable there is a circuit closer which the gun captain holds in his hand. Over each gun as shown there is an incandescent lamp which is in circuit with the cable. In making ready, the gun captain inserts the primer and arranges the cable as indicated. The gun is now ready to be fired. In the conning tower there is a row of push buttons just beneath the row of lamps. These lamps are used as indicators, and the push buttons control the current for firing the guns. Assuming for the sake of illustration that the gun shown in the cut has been loaded and is now pointed at the enemy, the gun captain, circuit closer in hand and with his eye along the sights, notices whether the aim is correct. If the gun is properly sighted, he closes the current. This action brings the lamp overhead to redness, indicating a completed circuit. At the same time a lamp on the same circuit, but in the conning tower, reddens, and this is the gunner's signal to the captain of the ship that this particular gun is ready. Should a gun captain notice the line of sight to be off the target, a touch of the button opens the circuit and signals the captain in the conning tower. When it is desired to fire the gun the captain of the ship presses his button, and this short circuits the indicator lamp in the tower, and also its German silver resistance. Practically speaking, the only resistance now in circuit is the lamp at the gun, as the current flashes up to the firing strength and the discharge takes place.

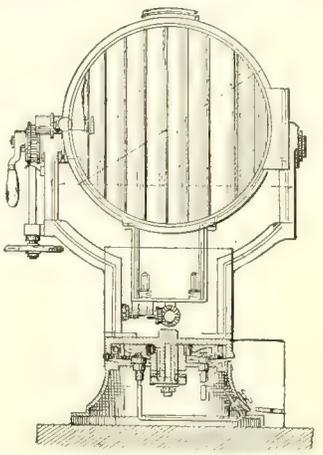

FIG. 7. ELECTRIC SIGNALING ON BOARD THE CHICAGO IN NEW YORK HARBOR.

The primers in use are of the same electrical dimensions as those employed for the service torpedoes. Their hot resistance is .05 ohm. Edison 24 candle power high economy 106 volt lamps are used. In addition to the two lamps in series in each circuit, there is also a German silver resistance of 175 ohms, which keeps the test current down to .18 ampere. With the current just mentioned the lamps give light enough to serve as indicators, but are not sufficiently bright to reveal the ship's position to the enemy. Okonite insulation is used on the conductors of the system.

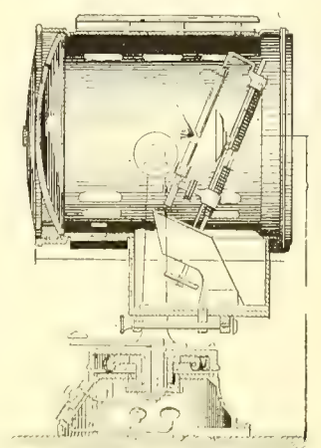

FIG. 8. ELECTRIC SIGNALING ON BOARD THE CHICAGO IN NEW YORK HARBOR.

The advantages of the electric firing system will be appreciated, for through it a broadside or any one gun can be fired from the conning tower.

The motor shown within the gun carriage, Fig. 5, is

used for training the gun. This machine is an old style 5 horse power Sprague motor wound for 105 volts, and when running under maximum load it takes 40 amperes of current. It is series wound. The reversal of the direction of rotation is accomplished by changing the direction of current through the armature. By throwing a clutch the gun can be trained by hand.

Electricity at the World's Fair.

It has been decided to locate the temporary power house at Jackson Park 100 feet south of the site of the transportation building. Engines and boilers sufficient to furnish 600 horse power have been loaned to the exposition authorities without charge, and so there will be no expense on this score.

Electrical Engineer Sargent of the construction department, representing Chief Burnham, issued circulars inviting bids for the temporary electrical plant over two weeks ago. These were mailed to all the prominent electrical companies of the country, eighteen or twenty being sent out. Mr. Sargent asked for bids for an installation capable of supplying 100 arc and 250 incandescent lights, together with a 80,000 watt generator for a motor circuit and such motors as may be necessary. This machinery is to be installed and rented to the exposition authorities until January 1, 1893.

This circular emphasized and increased the friction existing between the departments of electricity and construction. It was asserted on the part of the officials of the former that the circular was issued entirely without their knowledge. Some of the companies receiving it refused to put in bids, on the ground that propositions for the installation of electrical machinery should come from the head of the electrical department and not from the construction department. It was contended that one of the chief considerations that resulted in the appointment of Prof. Barrett was that he was free from entangling alliances with any of the electrical manufacturing or supply companies, and that he was thus peculiarly fitted to preside over the department. On the very first occasion, however, when impartiality needed to be assured, it was added, the task of supervising the letting was taken out of the hands of the man with whom all the companies were satisfied. There was talk of a petition to the board of directors of the exposition asking that all contracts for electrical supplies be made through Chief Barrett.

Before this Mr. Sargent had talked of resigning his position as consulting electrical engineer to the department of construction. As can easily be conceived, the place was, and is, a delicate one, combining tendencies that are now pulling in opposite directions. It is not strange that Mr. Sargent should be willing to resign it, especially as he could well afford to devote all his time to his private business. After the circular was issued, and the ensuing dissatisfaction was openly expressed, on July 23d, Mr. Sargent did actually send in his resignation to Chief Burnham. On the same day the two gentlemen named had a long conference, however, and the upshot of it was that Mr. Sargent withdrew his resignation. He now declares his determination to stay in his present position until the fair is over.

This is the situation as it is to-day, and this is why so little, comparatively speaking, has been accomplished in the electrical department of the World's Fair. In plain words, Chief Burnham and Mr. Sargent on one side and Prof. Barrett and Mr. Keller on the other have widely divergent views as to who should have charge of work in which both departments are interested, as in the case of the temporary plant. On the one hand it is urged that the work is clearly a phase of the general construction, while on the other it is asserted that, as it is purely electrical in character, it should be designed and supervised by the electrical department, only the actual work of construction falling within the scope of Chief Burnham's department. This state of affairs cannot fail to work injury to the department of electricity. Indeed, it has already done so. It is with the hope of hastening a happy solution of the difficulty that the WESTERN ELECTRICIAN has endeavored to set forth the facts clearly and impartially, without assuming to lay the blame on any one. But there should be some clear understanding by which these vexatious delays and disagreements could be avoided. There is enough work to be done, without the representatives of different departments contending with each other. The matter has already been called to the attention of the executive committee. It is to be hoped that it will speedily arrive at an equitable basis of adjustment.

A realistic miniature model of the World's Fair is now on exhibition at the old exposition building on Michigan avenue. It covers an area of [illegible] square feet at the south end of the building. The model occupies the center of the room and is about level with the floor. The low roof has seventy-five incandescent lights, which give the effect of

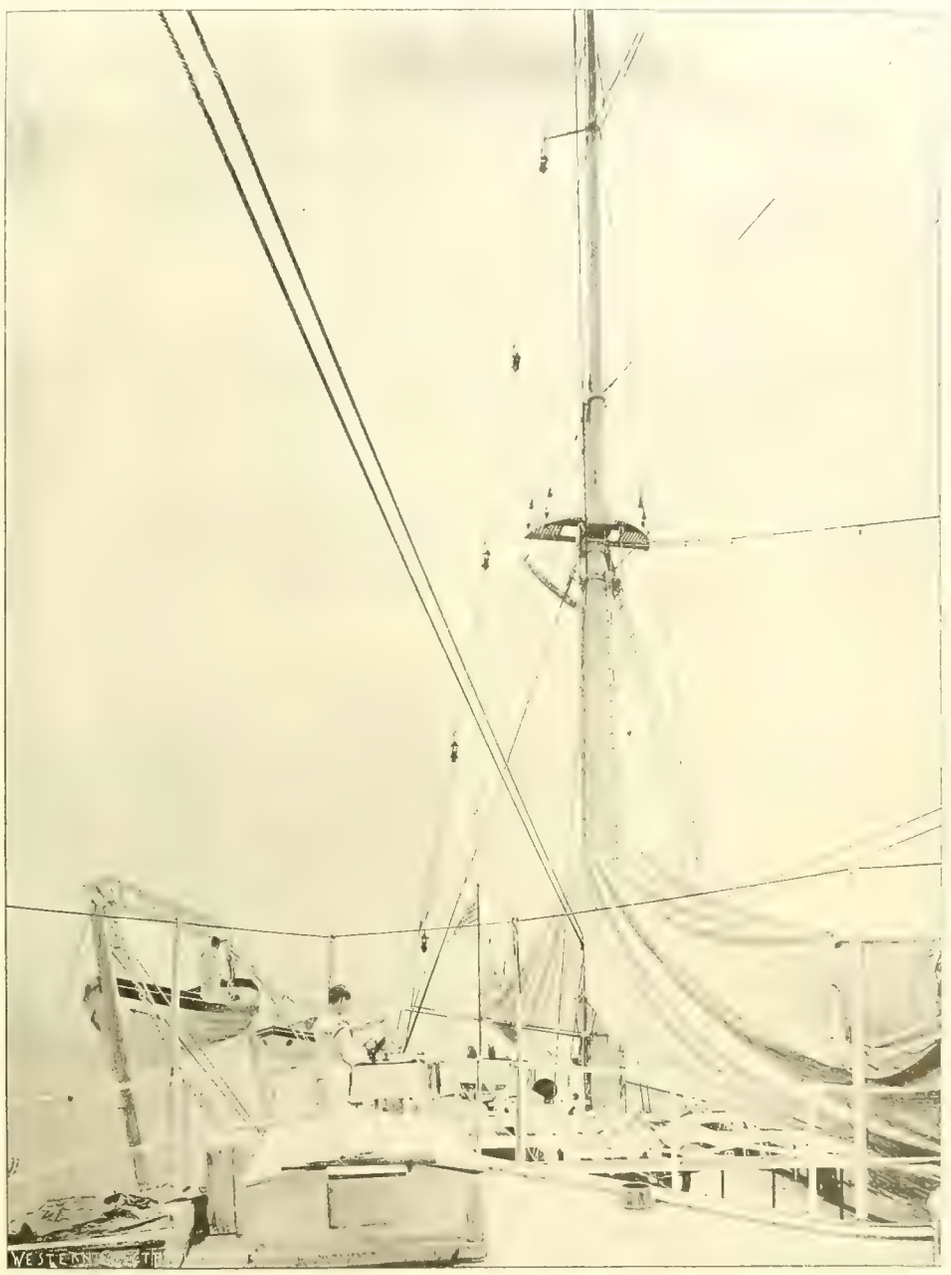

FIG. 2 ELECTRIC SIGNALING ON BOARD THE CHICAGO IN NEW YORK HARBOR.

weary of looking at the miniature are given a chance to [illegible] the lights changing auto-

World's Fair officials and adopted by them, not, however, until it had been published in this journal, May 9th.

Three bids for supplying the temporary plant at Jackson park were opened last Monday. They were from the Thomson-Houston Electric company, the Edison General Electric company and the Western Electric company. The award was not made at that time, however.

Col. Clowry's committee on electricity held a meeting on Monday afternoon at Chief Burnham's office. Prof. Barrett and Secretary Hornsby, representing the department of electricity, were present. The relations of the two departments were discussed, and various propositions were advanced, but no conclusion was reached, the committee adjourning to meet on Tuesday at 2 P. M., in the office of the electrical department.

Electric Motors for Switching and Suburban Traffic on Steam Railroads.

As a rule the steam railroad journals of the country have been very conservative in commenting on the application of electric motors to railway work, other than in the line of street cars. The following editorial, therefore, from the *Railroad Gazette*, second in influence to no paper of its class in the United States, will be accepted as significant:

"There is renewed activity among electric motor companies in matters pertaining to large motors for heavy work, such as switching freight in cities where smoke is objectionable and for elevated roads. Two of the largest companies believe that they have solved the problem, and

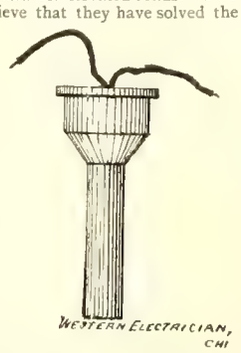

FIG. 6 ELECTRIC SIGNALING ON BOARD THE CHICAGO IN NEW YORK HARBOR.

one of them will at once build a motor with a capacity ranging from 500 to 700 horse power and a hauling power equal to any steam locomotive with 45,000 pounds on the drivers. This has been rendered practicable by recent improvements in motors, of which the slow-moving armature and the subdivided field are probably the most useful for heavy work. Railroads in such cities as Chicago, where a city ordinance prohibits the use of locomotives that emit smoke in any considerable amount, are now compelled to use a non-smoking fuel, such as coke or anthracite, or put on a device for preventing the formation of smoke, the action of which is acceptable to the city inspector. As such devices are more or less ineffective, even in their best form, it has been found necessary on at least two Chicago roads to resort to anthracite coal, at a cost of $4 to $4.50 per ton on tender, to meet the requirements of the law. Where steam costs at this rate it cannot be difficult to construct an electric motor which will work with at least equal economy, as cheap coal can be used in the stationary plant which furnishes the electric current. With such advantageous conditions, the difficulties in the way of the use of the electric motor for suburban work are mainly in the mechan-

ical devices in the motor itself and the arrangement of the conductors. The electric companies feel sure that they have now removed all these difficulties, and they will make a trial of a heavy motor to prove what can be done. When the railroads of this country are assured that an electric motor of sufficient power to switch trains at terminals and to haul suburban traffic can be built of as simple design as those now used for street railroads, and can be run with reasonable economy of fuel, there will be no lack of opportunities for trial on a large scale."

Electric Lighting in Paris.

Electric lighting in Paris has lately made rapid strides, and several large central stations have been erected dur-

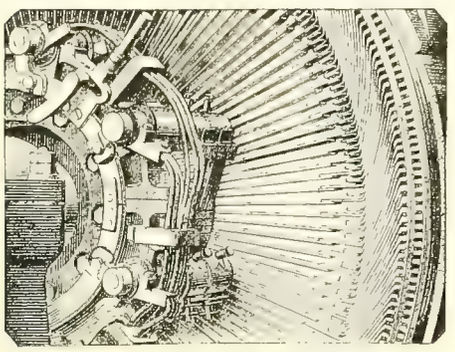

FIG. 2. ELECTRIC LIGHTING IN PARIS.

ing the last year. The great station at Rue des Dames de Batignalle has already been illustrated and described in the WESTERN ELECTRICIAN, and in this issue are presented views showing work at the new station at Faubourg Montmatre, which is furnishing lightts on many of the great boulevards and the adjoining streets and avenues. The building is a large iron structure, with an adjoining basement utilized for a boiler room, in which there are four high pressure boilers, furnishing steam for four 300 horse power triple expansion vertical engines, coupled to four large multipolar dynamos. The front part of the building is used for switchroom, storeroom and offices. Room is also provided for adding a large accumulator plant, which is now being considered. The generators employed in this station are of a special design, and are multipolar double dynamos. Fig. 1 gives a perspective view. The machine is composed of a double ring armature, each ring having its own field of induction and its

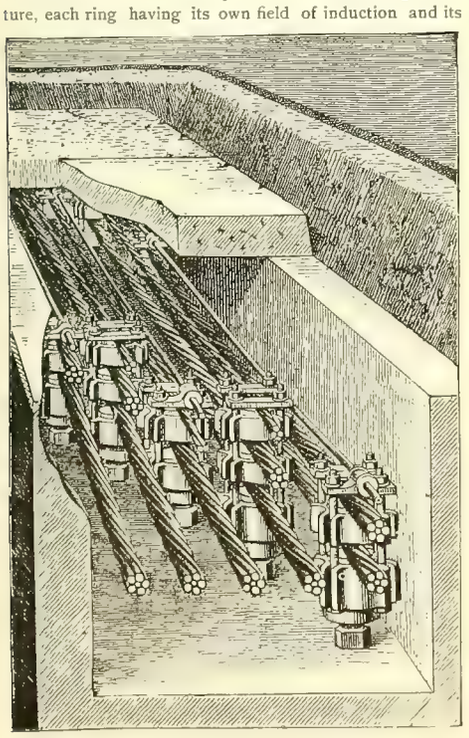

FIG 4. ELECTRIC LIGHTING IN PARIS.

own commutator, so that it actually comprises two dynamos united on one shaft. The advantage of this, it is claimed, is found in the greater uniformity obtained in operating the dynamos on the three-wire system, than could be secured in coupling two separate dynamos in series. This double dynamo requires a 300 horse power engine to operate it and furnish 1,000 amperes at 125 volts. It is operated at 130 revolutions. The diameter of the armature is five feet four inches. The iron core is laminated, and has the shape of a Gramme ring, but the mode of winding is similar to the Siemens multipolar dynamo. Its winding consists of only one layer of square copper bars, covering both the outside and the inside of the ring; these are joined at their extremities by flat copper strips running in a curve to the right on the front of the armature, and at the junction of this are connected with radial copper strips leading to the commutator. On the inside between the two ring armatures the copper bars of both are connected in such a way as to form a continuous circuit. The field consists of eight poles, and is built as a concentric ring of eight electro magnets, of 8¼ inch diameter, with a winding of eight layers of No. 8 wire B. & S. gauge. The pole pieces are large, and joined together in pairs, thus forming a ring which surrounds the exterior of the armature. The exciting current for the field magnets, which are connected in series, is taken from the bus bars of the switch-board, and amounts to 25 amperes or about two per cent. of the total output. The commutator is large, its diameter being about one-third of the armature. It is furnished with eight sets of brushes coupled in multiple. Fig 2 shows a section of the armature and commutator, showing the setting and arrangement of the brushes. The efficiency of this dynamo is claimed to be high. An important feature claimed is that it will endure a very long run without heating on account of the large heat radiating surface of the armature.

On account of the arrangement of this double dynamo the two armatures always work together, and consequently the arangement of the switch-board is made on the same principle, so that meters and switches always appear in pairs. Fig. 3 represents the switch and meter arrangement, *E E E* being the bus bars composed of heavy round bars clamped together, while *F F* represent two

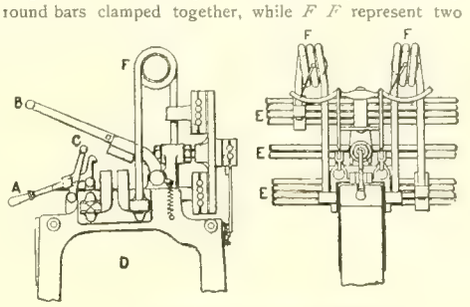

FIG. 3. ELECTRIC LIGHTING IN PARIS.

ampere meters, remarkable for their simplicity of construction. A heavy copper wire is turned so as to make three sections of a spiral. Through the center turn is bored a small hole which supports an axle carrying a spool of fine wire in the center of the coil. On the outside is an indicator needle showing by deflection the amount of current passing through the spiral. The switch is so arranged as to break both the distributing current from the dynamo and also the exciting current for both fields. In closing the switch *B* is pressed down and forms the connection between the brushes and the bus bars. At the same time the catcher *C* on the lever *A* clasps a protruding point on both sides of the main lever, keeping it in position and making the connection for the field. In opening the switch *A* is pressed down until the catcher detaches itself and the lever *B* flies up by the action of a spring.

The distribution of current is carried on through an underground conduit, Fig. 4. This is built of cement. In the bottom of this conduit are five rows of iron posts placed at intervals of fifteen feet. On these posts are porcelain insulators held by four iron bolts. On and between these insulators are suspended bare copper cables.

The conduit is covered by slabs, cemented together to prevent surface water from soaking through. The merits of this system are cheapness, high insulation and great facility in handling and splicing the cables. The heavy feeders are placed nearest to the bottom of the conduit, and the mains and service wires in the upper rows so that the work of replacing a cable with one of heavier size is a comparatively easy task.

The station at Montmatre has been in operation only a short time, but is already taxed to the full capacity, so that an extension of the plant is now under consideration. The illustrations are reproduced from *Electricite*.

THE BOOK TABLE.

PRIMARY BATTERIES, by Henry S. Carhart, A. M., Professor of Physics in the University of Michigan. Published by Allyn & Bacon, Boston. 103 pages, 67 illustrations, type page 3½x5½. Price $1.50.

This is probably the only book in the English language which gives the principles involved in the construction, operation and theory of primary batteries systematically arranged. It will be of great value to students and all those who have anything to do with primary batteries in practical use or in laboratories.

The book gives the latest theories relating to voltaic [illegible] is well printed and profusely illustrated.

Accumulators in Belgium.

[illegible] read with interest: "The judgment given against M. Gadot and his colleagues in the proceedings with reference

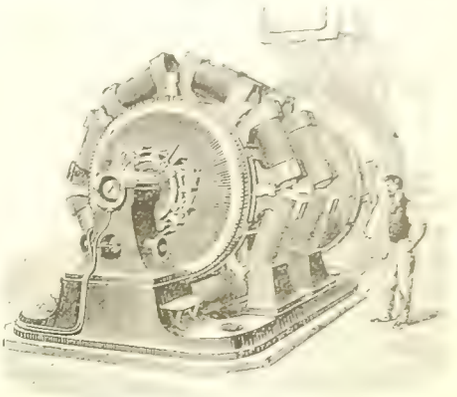

FIG. 1. ELECTRIC LIGHTING IN PARIS.

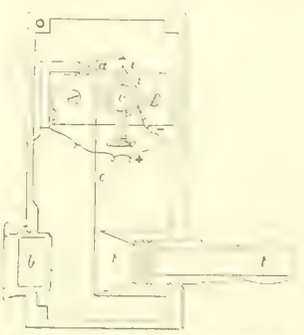
to accumulators has been confirmed in the higher court, and much uncertainty has thus been removed. The Julien company, which owns the F. S. V. patents in this country, is extending its operations. M. Julien has obtained the right of using the Faure patents throughout the continent. Some large transactions are under discussion, and an improved type of apparatus is about to be manufactured. M. Julien has already received many requests for the right of making use of these patents. M. Julien first introduced accumulators in Belgium, and after overcoming various difficulties, he now seems likely to be thoroughly successful."

Apparatus for Indicating Variations of Pressure in Gaseous Currents.

In the accompanying diagram is shown the method of operating an electrical device invented by G. and L. Richard for the purpose of indicating automotically slight variations of pressure in currents of gas. It is very small but extremely sensitive, being capable of responding to variations of pressure which are no greater than the pressure of a column of water a few hundredths of a millimetre in height. The essential features of this apparatus are as follows: A metallic box is placed in communication by



APPARATUS FOR INDICATING [illegible] PRESSURE IN GASEOUS [illegible].

means of a tube *t* with the conduit through which the current of gas is passing. The tube is closed by a clack valve *c*, made of light metal, movable around an axis *x*, and balanced in such a way that when the pressure is lower than the limit for which the apparatus is set, it remains, closing an electric circuit [illegible]. In this circuit a coil may be placed. A box [illegible] charged with cotton [illegible] events dust and similar matter from entering the mechanism. Suppose a lowering of the pressure to take place, then the clack-valve *c* closes the orifice of the tube *t* and the circuit is thus open and the current no longer passes. The apparatus is capable of having its sensitiveness modified to suit any given circumstance. It is capable of many industrial applications. For example it may be applied in order to regulate ventilation; also to certain forms of slow-combustion stoves, etc. [illegible] from the London

COPYRIGHT.—Not only the title, but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago Postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions, foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity, or any of its practical applications, is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—*the only general electrical paper published in the West*—thoroughly covers a territory *as much as any*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring Western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be promptly furnished on application.

[illegible] made [illegible] the Dominion [illegible] telephone and electric apparatus of all kinds for communi-

the electric railway best serves the public on account of the speed attainable, the absence of dirt and noise, and its numerous other advantages, has long been established, and now it is shown that the new system is equally advantageous to the operating company from an economical standpoint. This combination will work wonders toward extending electric railways.

CABLE railways, once so popular on the Pacific coast, have fallen in the public estimation of late, and now it is possible to dispose of stock in cable roads only at a sacrifice. A Los Angeles company which has expended over a million in cable construction has passed into the hands of a receiver, and it is expected will soon be disposed of and transformed into an electric system. Examples of this kind are presenting themselves so regularly of late that they fail to excite much attention.

OUR New York correspondent mentions a remarkable instance of profit making in electric railway property in the sale of the Rapid Transit street railway of Newark, N. J., for an advance of $800,000 over the price paid by the vendors. The latter purchased the road about a year ago for $200,000, and accordingly made 400 per cent. on their investment in that space of time. This is of course an unusual case, and one that cannot be taken as typical; but it is nevertheless true that street car companies operated by electricity have almost invariably proved paying investments, both in large cities and small towns.

THE announcement that an American steam railroad company would endeavor to negotiate a loan of $5,000,000 in London attracted considerable attention in financial circles not only in England but also on the continent. This was due largely to the fact that the company in question had been obliged to withdraw its suburban trains owing to its inability to compete with the electric road which was recently opened in the territory which it covered. Not long ago our friends across the water expressed the belief that much of the advancement made in electric railways in this country was on paper, but now they are hesitating about putting money in steam railroads, especially those that are liable to invite competition from electric railways.

THE idea of operating submarine torpedoes by means of a reflected view—a sort of camera obscura arrangement—and an electric exploding device, illustrated in this issue, is characteristically French. It reads like one of Jules Verne's scientific extravaganzas in fiction. We may be permitted to doubt the availability of the scheme in actual warfare, but there is a certain glamor in the idea of sitting "comfortably in a bomb-proof station on shore," watching the enemy's fleet coming on with the confidence of approaching triumph, and then calmly touching the vessels off one by one as they come up the fatal spots, until all the ships are destroyed or in retreat. What could be more simple? Possibly the enemy might interpose objections, or the apparatus might get out of order; but the idea is very picturesque, nevertheless.

A BRIEF article from the *Railroad Gazette*, copied on another page, is worthy of attentive perusal. It is entirely within the bounds of possibility—indeed it is not unlikely—that electric motor cars may yet come to play an important part in the switching yards of the great railroads of the country. Our contemporary points out several advantages that the innovation would have in certain cases, and their pertinence is apparent. The remarks of the *Gazette* in relation to the application of electricity to suburban traffic, however, will not be received by the electrical fraternity so favorably. This branch of electrical locomotion is spoken of as yet in the future, whereas the experience of Boston, Pittsburg, Rochester, Minneapolis and other cities shows that a large suburban traffic can be handled easily and rapidly by the electric system. This feature of the business is no longer in the conjectural or experimental stage. It is an assured success.

[illegible] issue of the WESTERN ELECTRICIAN there is presented a series of views illustrating the electrical signaling apparatus with which the cruiser, Chicago, of the White Squadron is equipped. The movements of these war ships have excited the greatest interest in New York, and on the night of the search light drill there was much enthusiasm. The cuts, which are reproductions of photographs taken [illegible] WESTERN ELECTRICIAN, will enable the inland reader, as well as those in New York who had not the opportunity to go aboard the vessels, to obtain as correct an idea of the Chicago's outfit as though a personal [illegible] interest of electrical [illegible] with the thoroughness with which all work has been carried out. Naval men realize that cleanliness is a virtue, and the appearance of the machinery on the Chicago convinces one that some one has had to practice what another has preached. A few of the many so-called wiremen and expert dynamo tenders might be set thinking by a visit to the Chicago.

RAPID transit continues to occupy the attention of the people of New York city. Commissioner Steinway repudiates the ideas presented in an alleged interview with him which have already been criticised in this paper. Last week Frank J. Sprague called him to task, and the commissioner immediately disclaimed responsibility for the statements attributed to him. He said that he looked upon the Greathead system as one of the best for work of that kind.

There are, however, many features of the system proposed by the commission in its report which have passed without much notice, though they can scarcely receive the approval of the people. In the first place the idea of having a common track for the down town district would be a grievous blunder, and one that would soon be recognized in practice. But the people of the city and the newspapers do not seem to appreciate the fact that the rapid transit they are clamoring for cannot be secured as long as measures of this kind are seriously considered. The overcrowded condition of the 'L" road under the present administration would be repeated only in a worse form in the new system.

STORAGE battery cars will soon be seen again in the streets of New York. The recent decision of Judge Coxe has given the capitalists controlling the patents of Brush the assurance they required and now they are proposing to put the cars in operation that have been idle since January last.

This is not all, however. In addition to the sixteen cars formerly used in New York city further equipment will be added and the entire Fourth avenue district served by storage battery cars provided the tests prove as favorable as the company anticipates. The people of the district are in favor of the storage battery car and will have no other.

The outlook for the system in other cities is equally attractive; for instance, in Washington, there will be 44 cars put in operation at once. Indianapolis and New Orleans are about to install initial systems. If they prove successful, extensions will follow. The storage battery now has an excellent opportunity, one which its advocates have long been desiring, and if it does not now prove successful it will not be because it has not had a fair trial. Much is expected of the system and its projectors will be obliged to go to work at once to develop it.

THE disciples of Morse will be interested in the convention of telegraphers at Washington this month. The Old Time Telegraphers and the Military Corps will as usual meet at the same time and place. It is probable that further measures will then be taken to secure proper recognition by Congress of the telegraphers who risked their lives and endured great hardships in the interest of their country during the civil war. It cannot be denied that their services in those trying times were of great value. They were exposed to all the dangers of the regular troops and their position was even more trying than that of the men about them actively engaged in the conflict. Yet Congress has repeatedly seen fit to deny the surviving members of the telegraphers' corps the recognition which is their due—an unjust discrimination. They only demand an official acknowledgment of their services and an honorable discharge. Little enough for the services they gave their country in its hour of trial.

But there is another feature of this meeting of veteran telegraphers which will be of general interest. As Washington was fixed as the place of meeting it was thought appropriate to invite Mrs. Roswell Smith to attend. Mrs. Smith was a prominent figure in the struggle which Morse made in Washington to secure an appropriation from the government for his first telegraph line. This lady had the honor to convey to Prof. Morse the news of the successful termination of his struggle. To show his appreciation of the interest displayed the inventor conferred upon Mrs. Smith, who was then Annie G. Ellsworth, the honor of sending the first message over the new line. It is probable that Mrs. Smith will relate some personal recollections of Prof. Morse, which will no doubt be very interesting, as Mrs. Smith's father, who was then commissioner of patents, took a great interest in the telegraph project, as in fact did all his family, and Mrs. Smith had an excellent opportunity to study the character of the man in whom so much interest was shown, even at that time. Her presence therefore at the Washington reunion will be very appropriate.

Goubert's Watt Meter.

The accompanying illustrations represent a new watt meter designed by M. Goubert of Paris. In principle it is entirely different from the ordinary watt meters and ampere-hour meters, and combines novel and interesting hydraulic and electrical features.

The construction is simple. Fig. 1 gives a view of the apparatus showing the several parts. *A* is a dynamometer inclosed in a box and having an oscillating extending axle. It is furnished with a spiral flexible tube, the

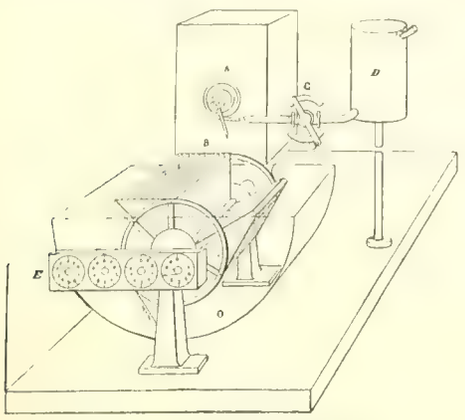

FIG. 1. GOUBERT'S WATT METER.

center of which is fastened on the axle while its other end is connected to a water reservoir *D*; this is so arranged with feed water and overflow pipes that the pressure in the spiral tube is kept constant. A valve *C* opens and closes for the flow of water into the tube, and at the same time acts as a switch for the electric current, so that the water is stopped simultaneously with the current. Below the outlet of the spiral tube is a hydraulic wheel *B* composed of three buckets, each of which is divided into ten compartments. The shaft of this water wheel is joined to a velocimeter *E*, which registers the number of rotations, and a trough *O*, which receives the water from the bucket and leads it away through a waste-pipe. The action of this mechanism will be readily understood. When the switch-valve is turned, the electric current is closed and the water commences to flow. If the load is very small no visible action will be noticed on the dynamometer and the faucet as shown in Fig. 2 will spout its water in the direction of *O* past the bucket *b* of the water wheel. When the load increases, the faucet will move to the left and take the position 1, 2, 3, 4, etc., in accordance with the energy acting on

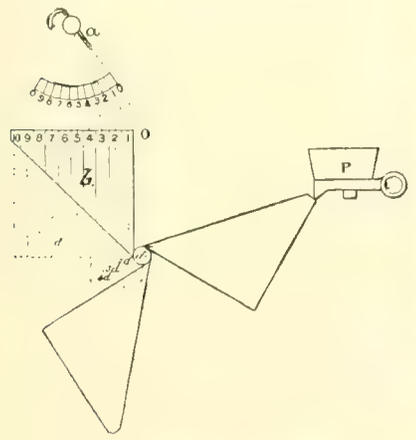

FIG. 2. GOUBERT'S WATT METER.

the dynamometer. The water will flow into the compartment of the wheel corresponding to the position of the faucet, and when this is filled the weight of the water will trip the counterweight *P* and turn the wheel one-third of a revolution. The force of the water on the shaft *d* is equal for any part of the wheel, but the time required for filling the compartment decreases toward the periphery, thus increasing the rate of the rotation of the water-wheel in accordance with the load on the dynamometer. Each rotation represents 100 watts, which is recorded on the velocimeter.

This hydraulic meter possesses the advantage of great simplicity, and has no complicated mechanical movements, but it remains to be seen whether its accuracy is proportional to the simplicity of construction. The illustrations are reproduced from *L'Electricien*.

The city council of Hillsboro, Tex., has decided to erect an electric light plant.

Electricity for Submarine Torpedoes.

The advancement in the application of electricity to the operation of implements of destruction employed in modern army and navy practice is becoming more marked. The main idea in the recent developments in torpedo practice has been to obtain a high degree of exactness in manipulation, and to protect the operators from any possible danger. This has been practically accomplished by the employment of electrical power. By aid of the system illustrated in the cuts, the defense of a harbor or city may, it is claimed, be left to the care of two persons whose strategic abilities do not need to exceed that of an average boatswain. These defenders can be seated comfortably in a bomb-proof station on shore, while the image of the harbor with the enemy is reflected on a table in front of them On the same table are marks which indicate the location of the submarine torpedoes. When a man-of-war is seen to approach one of the marks, it is only necessary to turn a switch and blow up the non-suspecting enemy without exposing themselves whatever.

In the accompanying illustration Fig. 1 represents a diagrammatical sketch of two such torpedo stations, the location of which should be on opposite sides of a harbor or bay, and as nearly as possible on the same level. In each station is a disk *A* carrying a telescope *I* mounted on a movable stand. This is furnished with a lever, which by turning the telescope sweeps the edge of the disk. From the torpedo four wires are connected to different contact points on the edge of the disk. The telescope stands are joined through a switch *B* to a battery *P*. When now an enemy approaches, the two operators being in telephonic connection with each other, direct their telescopes and all they have to do is to follow continuously the movements of the vessel If in turning the two telescopes, the levers on the disks of both instruments strike the same contact point at the same instant, the current is closed and the torpedo fired. The contact points on the disks are adjusted in such a way that the closing of the circuit can only take place when the vessel is exactly over one of the torpedoes.

Fig. 2 represents another plant on the same principle. In the ceiling of a dark chamber is placed a mirror reflector under an angle of 45 degrees; this is reflecting a picture of the surrounding harbor on a polished table placed below the opening in the ceiling. On the table is marked

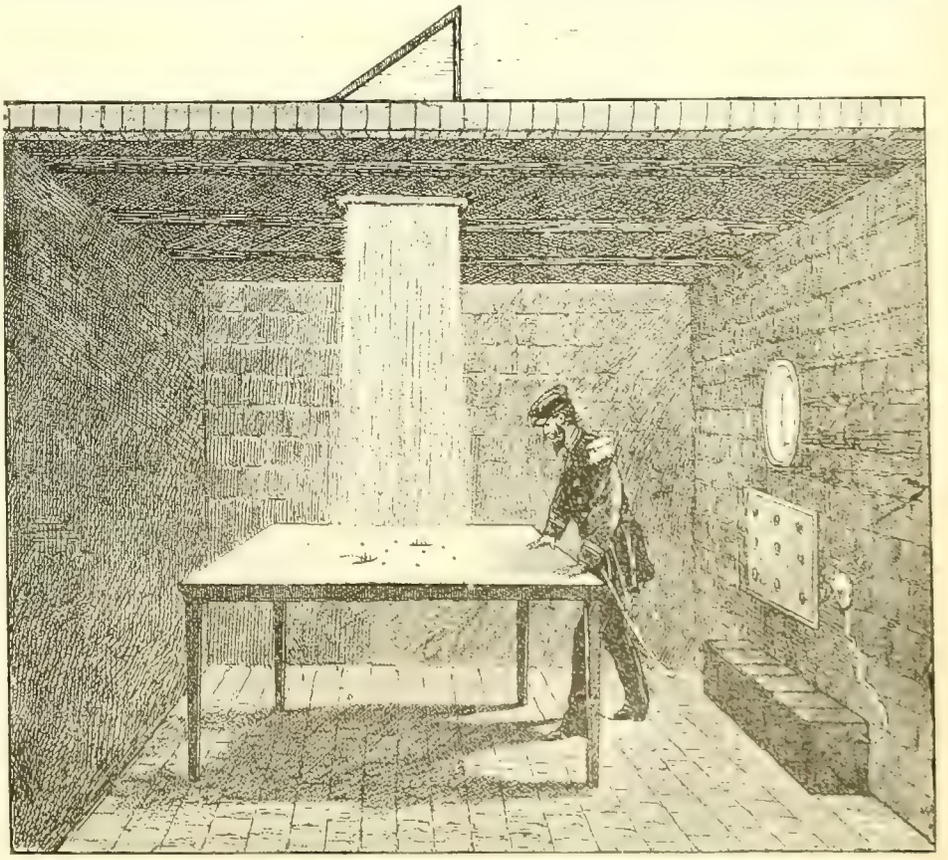

FIG. 2. ELECTRICITY FOR SUBMARINE [illegible]

the exact position of the torpedoes, and whenever a vessel gets in close contact with one of these marks, the operator presses a button, closing the circuit, and exploding the torpedo. The illustrations are taken from the [illegible].

The Allgemeine company of Berlin, Germany, is to construct two electric tramway lines on the Sprague system at Stockholm and at Kiew.

A Prediction from San Francisco.

this prediction:

youthful helper, Smalley, have looked fairly forward to this time, would not their eyes have brightened, when, in 1534, they were laughed to scorn by neighbors for discovering the [illegible]

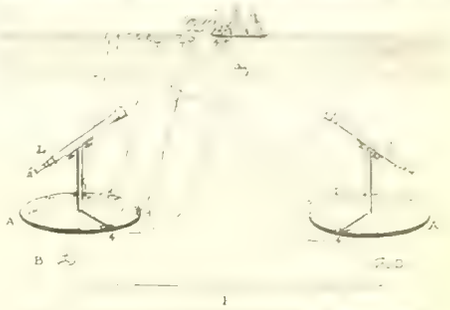

FIG. 1. ELECTRICITY FOR [illegible]

We of old California can look back and see our mountains on all sides, our rich and fertile valleys, our prosperous mining camps, and then ask ourselves what one agent of all others has been the means of developing them. The answer is, water. From one end of our glorious state to the other the perpetual snows of the Sierras yield an abundance of water, never-ceasing, powerful water, placed at our service by the hand of God; made infinitely more powerful by another Providential gift—gravity. Unprofessional as it may seem, in my case, it is with misgiving that I assume to be a prophet, and yet, inspired by the occasion and encouraged by your kindness, I will essay the task. I say to you now that I look to see a railroad operated with one moiety of this great power of ours, working quietly and rapidly, and connecting us with our brothers and the great markets in the East—all accomplished through

that inexpensive [illegible] water. Why, right in one county of this [illegible] to waste, is power enough [illegible] between San Francisco and [illegible] every two hours. Think of what [illegible] practically nothing but the [illegible] the plant and the [illegible] no noise, [illegible] and cast service."

Improved Governor for Steam Engines.

The accompanying cuts represent the improved Ball governor for the new engines manufactured by the Ball & Wood company of New York. This device constitutes a radical departure from all previous types of governors and has recently been patented by Mr. Ball. It has many elements of interest to electricians, as the Ball & Wood engines are especially designed for use in electric plants.

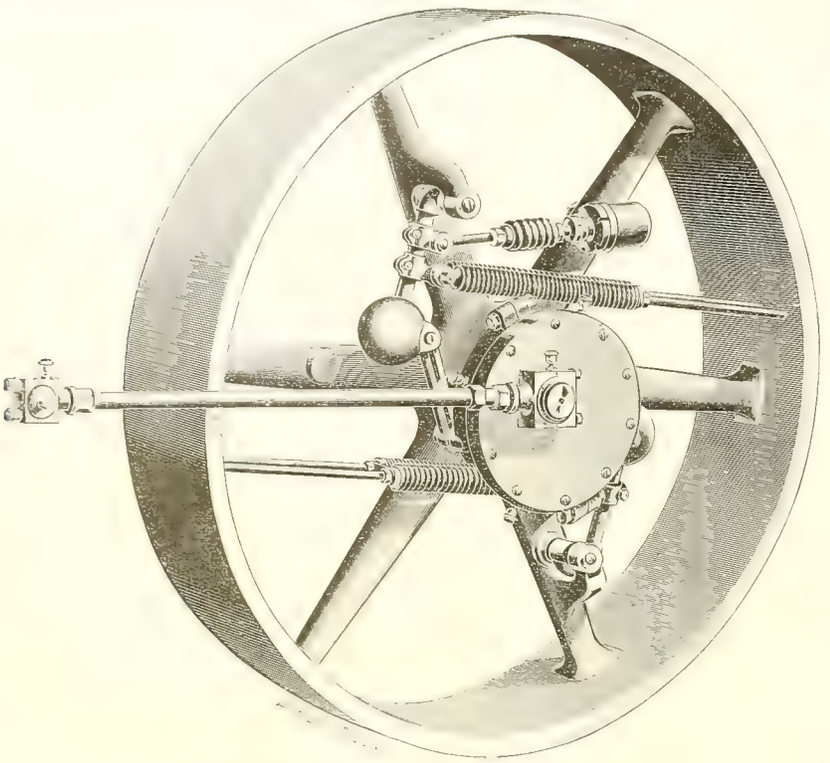

FIG. 1. IMPROVED GOVERNOR FOR STEAM ENGINES.

Referring to the cuts, Fig. 1 gives a perspective view of the governor, while Fig. 2 shows the details. In the latter the hub of the governor wheel is shown with the eccentric *A* bolted securely to its outer end, thus becoming practically apart of the hub. This eccentric is provided with an eccentric strap *B* made in halves and held in place on the eccentric by a flange on one side and the plate *C* bolted to the other side, as shown in the cut. The governor weights are connected by links *D* to studs in the side of the eccentric strap, so that the strap and plate *C* are turned slightly around the eccentric by the radial movement of the weights. This plate *C* carries a crank pin *E*, which, through the medium of a connecting rod, actuates the valve. The radial movement of the weights is thus made to turn the plate *C* around its center, which is eccentric to the shaft, and the crank pin *E* is thus moved through the arc of a circle whose center is the center of the plate, and the various points of cut-off are thus obtained. The curved path of the crank pin is made to give almost a constant lead to the valve until a very early cut-off is reached, when the lead rapidly disappears and prevents the engine from running away. A much better indicator card, with the earlier points of cut-off, is thus produced than would be possible if the crank pin moved in a straight line when [illegible] the point of cut-off.

In this mechanism only two rubbing surfaces are interposed between the shaft and the connecting rod which actuates the valve, the crank pin is practically the only rubbing surface [illegible] the only one constantly in motion relatively to the surfaces with which it is in contact. The other, the eccentric strap, only moves on the eccentric when the weights change their position. The wear here, [illegible] governor for [illegible] connecting the parts and keeping the [illegible] eliminated.

[illegible]

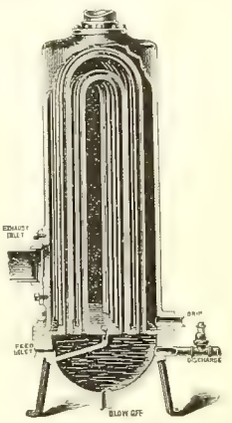
Electricity in Mining.

[illegible] of the [illegible] "Recent experiments in the utilization of electricity in this manner have been watched with a great deal of interest by miners and mine owners, and the success of the one at Telluride is of no small importance. The Gold King stamp mill at that point is now in successful operation from electricity conveyed two and one-half miles from an [illegible] alternating current dynamo, capable of developing 140 horse power, in turn operated by water power. The idea of [illegible] the great power of the mountain streams here [illegible] was originated with L. L. Nunn, who is interested [illegible] general manager of the Gold King property. [illegible] Telluride district have been [illegible] the new scheme, and [illegible] at once. The Belmont will convey power to its mills three miles and a half from the valley below, and others will follow as soon as possible.

"The saving to the mine owners and the increase in profits which will accrue to owners of mines high up the mountain or away from convenient water power can readily be seen. Mills can now be built at the mines, and the concentrates rather than the ores conveyed to the valley below. Mills that have been forced to burn timber or coal can through this method operate more economically, and the many low grade properties to which the expense of power has been a bar to operation can be worked to a profit. It is a step forward in mining, and when thoroughly understood and put into common use will add millions to the output of Colorado mines."

Improved Feed Water Heater.

In Radway's improved feed water heater, illustrated in the accompanying cut, the advantages of simplicity and reliability are claimed. Drawn seamless bent brass tubing is used, both ends being secured into the one head or tube plate expander. The shell is made of cast iron, and the settling chamber is divided into two compartments. As the water enters the heater it passes through the tubes and down into the settling chamber; then out at the top to the boiler. The chamber and tubes are from twelve to twenty times larger than the inlet and outlet of the feed, thereby allowing a slow and free passage of the water as well as plenty of time for the sediment to settle at the bottom, where it can be blown off. The area for the exhaust to pass around the tubes is from four to six times the size of the exhaust pipe, which is claimed to totally prevent back pressure.



IMPROVED FEED WATER HEATER.

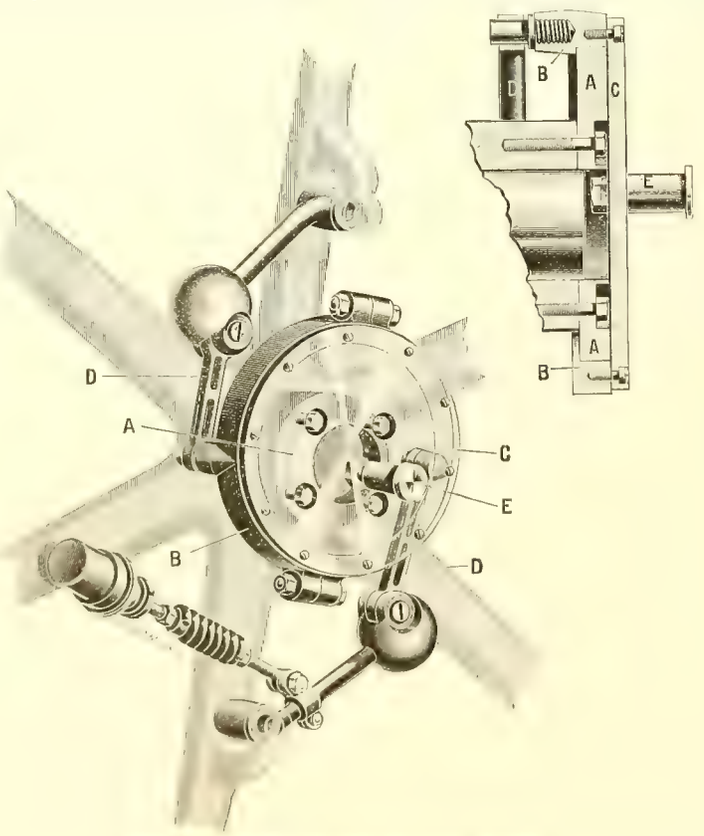


FIG. 2. IMPROVED GOVERNOR FOR STEAM ENGINES.

A recent number of London *Engineering* contains a brief account of the origin and growth of municipal electric lighting in Chicago.

Edison Convention in New York.

Secretary Jenks of the Association of Edison Illuminating Companies has issued the programme of the annual convention of the association at the Murray Hill hotel, New York, August 11th, 12th and 13th. It is as follows

FIRST DAY, TUESDAY, [illegible], 10 A. M.

Opening address by the president, roll call, election of officers for the ensuing year.

Report of executive committee and action by the association regarding applications for membership.

Report of secretary and treasurer.

Afternoon Session, 2 p. m.

Report of committee on the prevention of damage from crosses of high tension circuits, by C. P. Gilbert of Detroit, chairman.

Report of the committee on lightning protection, by A. E. Kennelly of the Edison laboratory, chairman, and the results of experiments at the laboratory on new forms of lightning arresters.

Report of committee on grounding the neutral wire in three wire systems, by A. E. Kennelly, chairman.

Report of committee on fuel gas, by J. R. Markle of Detroit, chairman.

A visit to the office and stations of the Edison Electric Illuminating company of New York, in response to an invitation from the company to inspect the special features of its three plantss and plans for the proposed comprehensive station near the City Hall.

SECOND DAY, AUGUST 12.

Morning Session, 10 a. m.

Address by officers of the Edison General Electric company as to matters of commercial interest to the association and the patent litigation.

Paper—"How to get a Paying Load for Stations," by William D. Marks of Philadelphia.

Paper on the meters in use in the station of the Brooklyn company, by R. S. White.

Paper—"How Can Our Association Best Serve Central Station Interests," by Frederic Nicholls, of Toronto.

Afternoon Session, 2 p. m.

Paper by W. L. Garrison of the Brockton, Mass., company. Subject to be announced.

Paper on "Important Details in Underground Conductors," by Mr. Stevenson of the New York Illuminating company.

Paper—"Some Practical Ideas on Distribution," by Leigh Carroll, of Birmingham, Alabama.

Paper by C. L. Edgar of Boston. Subject to be announced.

Paper—"Peculiar Features of the Edison Feeder System," by Wilson S. Howell.

"The Success of the Mutual Insurance Idea in Electric Light and Power Stations," by the secretary.

Paper by H. J. Smith of the New York Illuminating company. Subject to be announced.

Visit to the station of the Edison Electric Illuminating company of Brooklyn, in response to an invitation from the officers of that company.

THIRD DAY.

Visit to the Schenectady Works of the Edison General Electric company. Delegates will leave the Grand Central depot, New York, at 6 A. M. by special train with dining car attached, breakfast being served between New York and Albany. Arriving at Schenectady about 10 o'clock, the larger portion of the day will be spent in a detailed examination of the immense factories of the company, returning to New York in season to enable the delegates to attend the theaters or other amusements during the evening. Opportunity will also be given for a visit, by all members who may desire, to the lamp works of the general company at Harrison, N. J., the New York works, corner Avenue B and Seventeenth street, and the Edison Laboratory at Orange, N. J.

Electrical Census of the State of New York.

Horatio A. Foster has been appointed special expert agent for the collection of statistics relating to the electrical industries of New York. It is the intention of the census office to complete the work for the state of New York, and to publish the results in a special bulletin at the earliest practicable date. Mr. Foster will visit every central station, electric railroad and the more important isolated plants in the state, and assist their superintendents in correctly filling the official schedule. All schedules that have been sent to Washington are to be put into his hands for correction and verification. He will notify each company of the date when he will call for the purpose of finishing up its schedule, and will give all the assistance that may be necessary. Those particularly interested in the matter have issued a circular letter impressing on the superintendents of stations the importance of expediting the business in hand, as it is their desire to have the bulletin in question the first issued from the census department. To assist in saving time it is suggested that each superintendent should have a correct memorandum for Mr. Foster, covering the following details:

1. Average number of poles per mile.
2. Kind of wood.
3. Number of poles, part wood and part iron.
4. Total length of conductors on poles.
5. Total length of conductors on housetops.
6. Total length of conductors on bridges.
7. Total number of service connections.
8. Number of service connections on each alternating current main.
9. Total cost of all aerial conductors.
10. Total annual cost of maintaining all aerial conductors.

Where the Street Car Company Uses Sleighs in Winter.

The street car company in Montreal has to meet peculiar difficulties. It wants electric cars, but is afraid it cannot get them. The *Canadian Magazine of Industrial Arts* thus describes the situation:

"Although Montreal is behind certain other more favored cities in not having an electric street railway, many of our citizens would gladly welcome such a system of rapid transit, if it were practicable. It must be recognized that the City passenger railway has to contend with difficulties which are not encountered to so great an extent in those cities which have resorted to the desired system with more or less success. The winter's snow, which burdens our streets, presents the most formidable obstacle. It would be impossible to keep the tracks clear for many weeks—a necessity which now compels the use of sleighs instead of cars for the time being. In fact, the snow is packed down in the streets sometimes to a depth of from three to four feet. To have an electric system ready for the season when the track is clear would raise a serious problem as to the disposal of the large number of horses required by the winter sleighs.

"As the business of the city increases however, and the suburbs continue to extend, the need of some more economical and efficient method of transit becomes more and more felt, and surely Canada's metropolis should have a system adequate to the need. The problem is one which will more and more commend itself to those who regard with practical interest the city's progress."

Advantages of the Electric Street Railway.[1]

BY H. B. PRENDLE, B. S.

In this day of advancement it seems only reasonable to suppose that the already extensive and rapidly increasing use of electricity for street car propulsion is due to the fact that it possesses in a marked degree advantages over its competitors, steam, animal power and the cable. The belief is strengthened by the fact that among the street railway companies that have adopted it are to be found some of the largest and, at the same time, the most conservative companies in the country. Even if there were no other recommendations, its employment by such companies is good evidence that electrical propulsion of street cars has reached a state of perfection sufficiently high to warrant its general introduction

Nearly every one is familiar with the struggles through which the electric railway passed before it assumed a condition alike successful from a commercial and practical stand point, and although it may never be said of any system or method that it is entirely beyond the experimental stage, the electric railway is certainly beyond this stage in the ordinary acceptation of the term. Its permanency is unquestionable, and whatever changes may take place in the next few years will, in all probability, be in the nature of improved apparatus, the result of time and experience, rather than changes in the underlying principles of electrical propulsion. Roads now operating by animal power are fast changing to electricity, while the new road that does not employ it is the exception and not the rule.

The competitors of electricity in this field are steam, horses and the cable. In considering the merits of these systems steam may be omitted, as the past has shown that its use for street cars is not likely. There are but few cities in which permission could be obtained to operate steam roads and to use inside the city limits apparatus which brings to the already sufficient nuisance an additional amount of dirt, noise, smoke and escaping steam. Aside from these objections by municipal authorities, the economy of steam locomotives is far below that of the large stationary engines used in cable and electric systems, and their great weight causes a rapid deterioration in the track. Their use must be confined to the present long distance passenger and freight roads on which, as yet, steam exclusively has found employment. Many prominent engineers unite in saying that while up to the present time steam has been unchallenged on our great trunk lines, the marked development in electric traction points to a time not so very distant when steam shall have found a strong competitor in the electric current.

Leaving steam out of the question, of the three systems in common use to-day—the cable, the horse and the electric current,—the last named embodies all the advantages of the first two and lacks those features which render the use of the two former open to serious objection. In the question of the adoption of any system of car propulsion the first considerations are cost, operating expenses, safety, reliability and durability. Granting for the sake of argument that the operating expenses of electric, horse and cable roads are the same, are there not many advantages offered by the first over the second and third systems which would commend its employment and which would render its adoption certain? So far as the reliability of the system is concerned there can be little question. The experience of existing roads, many of which have known no tie-up, while others have only had such trouble of a trifling nature, is the best proof on this point. Experience has shown, too, that the durability of the apparatus has been all that could be expected of machines and appliances subjected to the wear and usage attendant upon this class of work. The more important parts of the machines are subjected to no wear and but little depreciation, and the parts wearing have to be renewed no oftener than like parts in stationary engines used for equally arduous work. The secular press has done its best to damage the system by exaggerated tales of the dangers due to electricity at high speeds. So far, in this country at least, there is no record of any person having met death by the current from an electric railway. Fear, then, in this direction is groundless.

Among the many advantages of electricity over the horse and cable systems is increased speed. In the cable and horse systems there is limit to speed, which cannot be exceeded in the latter and cannot be increased or diminished in the former without great wear upon the cable. In the crowded city streets and in the suburbs, the same speed, approximately, must be maintained. With the electric system all this is changed, and cars can be run at almost any desired rate. In the heart of the city they can be operated at three or four miles an hour, and, if necessary, at twelve or fifteen, as soon as the crowded streets are passed. What does this increased speed mean? It is equivalent to rapid transit to and from the suburbs for the traveling public, and an increased car mileage and increased receipts. At the same time, the ability of a motor car to haul one or two tow cars should not be lost sight of, as this renders it possible to double or treble the carrying capacity of a road. Compare the cost and operating expenses of these extra cars with the cost and maintenance of enough horses to do the same work in what, it must be

[1] *Engineering Magazine.*

[illegible] that high speeds are not suitable to city and suburban [illegible]

[illegible] the operation of the others may not be interfered with, in case [illegible] feeders is arranged so that the accidental breaking of the trolley wire cuts out but one section, and cars on either side can operate without difficulty. A more flexible system than the electric is not to be found. It can be extended to cover more territory at less expense than any other, switching and turn outs are easily accomplished, and can be used where revenue derived from cars operated by other systems would not pay expenses. Experience has shown that where electric railways have been installed in districts sparsely settled they have carried great activity in building of new homes for those whose income precludes their living within city limits.

These, are, briefly stated, some of the advantages which are brought by the use of electricity as a means of street car propulsion, but the most important features are to be found in the cost of installation and expense of operation. Those who are familiar with cable systems, with their enormous power plants and expensive conduits, can see at once how disadvantageous the comparison with the electric system will be. From reliable figures on first cost of equipment the average cost of five roads operated by cable in various parts of the country is $1,317,570.83, these roads averaging in length 7.15 miles, making the cost of installation per mile of road about $350 000. Five roads operated by horse power cost on the average $759,609.25, or $11,283 per mile. Five roads using electricity as a motive power cost on the average $242,628, or $36,000 per mile. These figures show in favor of electrical equipments per mile of track of $5,283 less than horse roads, and $314,000 less than cable. Assuming 10 per cent. for depreciation, the contrast between the three systems is not less marked. So much for original equipment, all of which is most favorable to the electric railway. A comparison of the cost of operation is more than likely to be incorrect, unless it is assured that the same expenses are included in each item which goes to make up the total cost of operation, and as comparison is the only method for attaining an idea of the comparative merits of systems so far as operating expenses are concerned, care should be taken that all comparisons are made upon an identical basis. From the report of the railroad commissioners of the state of New York for the year 1889 it appears that in the case of horse railways the average proportion of receipts to operating expenses for thirty-three roads was 79.39, while for electric roads, two in number, it was 53.50. From a similar report for the state of Massachusetts for 1889 the average proportion of receipts to operating expenses for thirty roads was 82.87, while for two electric roads it was 55.50.

From various reliable sources the following information is compiled regarding the operation of various electric railways:

These roads are [illegible] instances. The West End Street Railway [illegible] Boston is undoubtedly the largest [illegible] in the world, and the following data concerning its operations are of the greatest value. It [illegible] that this company has [illegible] buying current to operate certain lines, and also that this showing is in the face of the disadvantage of changing from horse to [illegible]. When the power stations are completed and in [illegible] are expected to

operate electric cars at an expense of not more than 20 cents per car mile

The company is operating about 75 twenty-six foot cars which during the month of May earned forty-four cents per mile operated, and forty-six and nine-tenths cents per mile operated during the first half of the month of June. When this long car service is extended the operating expenses will scarcely exceed 50 per cent. The net earnings of the company gained over the previous year $15,000 in May. Such is the result of electrical propulsion in the largest system in the world, and further comment is unnecessary.

Of all systems of street railway that which gives the quickest transit is the one demanded by the traveling public, and that which gives the best results is the one desired by the railway companies. Electric propulsion satisfies both requirements.

Lighting the Model City.

The *New Review* of London is publishing a series of articles on "A Model City; or, Reformed London." That in the July number treated of 'Lighting," and the portion on electricity was contributed by no less an authority than Lord Rayleigh. As a clear, though brief, resume of the best English practice, the article possesses much interest to American readers, and it is herewith reproduced in full:

Electricity is applied in two distinct ways to the production of light. When a current traverses a fine wire of metal, or other suitable material, energy is expended locally in overcoming the resistance of the wire and assumes the form of heat. the temperature of the wire rises until by radiation and communication of heat to the surrounding atmosphere a balance is established between the heat emitted and that received electrically. If the supply of electricity be sufficient, the temperature may attain to a red or white heat, and the wire becomes a source of light. This is the principle of the incandescent or glow lamp.

The economy of the lamp depends upon the temperature attained. Short of redness there is no luminous return at all for the electrical energy expended. Beyond that point the return is at first small, but gradually augments as a white heat is approached. The limit depends upon the properties of available materials. Among metals the most [illegible] platinum and iridium give way comparatively soon. The infusible character of carbon attracted the attention of inventors at an early date, and the [illegible] material for the wire or filament allows the temperature, and consequently the economy, to [illegible] possible with any metal.

[illegible] not, as might at first be supposed, an objection to its use, inasmuch as a platinum wire would [illegible] of oxidation by contact with [illegible] experience [illegible] disintegrated by the molecular bombardment to which they are subjected, even [illegible]

[illegible]

depends upon several considerations. In a few years the patents which now control the manufacture of lamps will expire, and the reduced cost will then justify a severer treatment.

The difficulties which oppose the attainment of a higher efficiency in glow lamps are evaded in the arc light. According to the discovery of Davy, near the commencement of the century, if two pieces of carbon, connected with a powerful source of electricity, are brought into contact, and then separated through a small space, a permanent current, constituting the electric arc, establishes itself across the interval; and the passage of electricity gives rise to a light of great intensity. It is however, a mistake, although a common one, to suppose that the arc itself is the principle source of light. A little examination shows that the light comes rather from the white hot carbons upon which the arc abuts.

It appears, then, that both electric lights have their origin in incandescent carbon. Nevertheless, there are many important points of difference. In the glow lamp the carbon must be retained intact; and this, as we have seen, imposes an early limit upon the admissible temperature. In the arc light the carbons are undergoing rapid disintegration all the while, and the temperature is much higher. The greater efficiency of the arc as a transformer of electrical energy into light is undisputed; but it is equally certain that this advantage is not without its attendant drawbacks In the first place the gradual consumption of the carbons implies a more or less complicated mechanism for preserving the proper interval between them, and their renewal means daily attention. Another difficulty is that of adequate subdivision of light. For domestic purposes we do not require single lights of 1,000 candle power. A hundred separate lights each of 10 candle power are really worth much more. Again, in spite of recent improvements, arc lights are rarely quite steady. There is also the question of color. The blueness with which arcs are often credited is an illusion dependent upon contrast; but the fact remains that the white light which they supply is thought to be more trying to the female complexion than the yellow color of candles, approximated to by glow lamps. For picture galleries, factories and shops where the nice discrimination of colors is important, arcs are unrivalled, as well as for special purposes, *e. g.*, in magic lanterns and lighthouses, where great concentration is an advantage.

The comparison of the two ways of applying electricity thus leads to the conclusion that there is a field for both. Large buildings and open spaces may well be illuminated by arcs, but for ordinary domestic use the superiority lies unquestionably with the glow lamp.

How far the electric glow lamp will displace other illuminants is a question upon which opinions naturally differ. Experience already shows that a large number of people prefer electricity even at a cost amounting to several times that of gas. In many cases the comparison to be made is rather with candles than with gas, for the latter is not usually considered good enough for the drawing-rooms and dining-rooms of those who can afford to pay for comfort. Modern paraffin lamps are, it is true, a great improvement upon those of our youth; but here arises the question of domestic labor. Electricity is as convenient as gas, while it consumes no oxygen, smokes no ceilings, and needs no matches. The ease with which it can be turned off and on by a switch near the door as a person leaves or enters a room offers a great opportunity for economy. A good deal probably still remains to be done in the way of finding the best disposition of lights. The comparative absence of heat allows of situations impossible to other illuminants, of which advantage has not yet been fully taken. Those who indulge in the luxury of reading in bed have a grand time before them. It seems likely that many dark underground places may be rendered much more available than at present by the use of electricity.

The vaunted coolness of electric light may seem paradoxical after what has been said of the high temperature of the filament. These apparently contradictory characteristics are really connected in the closest manner by the laws of radiation. The exceedingly high temperature of the filament is the very reason of the small heat in comparison to candle power. How far the coolness will tell in favor of electricity remains to be seen. One can imagine that in cold weather the heating effect of gas and oil would be missed by those unable to pay for ample firing.

So far we have been dealing with the private consumption of electricity, if such a term may be allowed. A still more important branch of the subject relates to the character of the supply. It may be taken for granted that it will be public, analogous to the usual supply of gas and water. At the present time, it is true, many of the theaters, hotels and clubs possess private plants and supply their own needs. This arrangement is not likely to last, unless, perhaps, in the case of institutions of exceptional magnitude. It is in the main a result of the Electric Lighting Act of 1882, which in the supposed interests of the community threw such impediments in the way of enterprise as to cause London to fall into the rear of American villages and distant islands of the Pacific. During the last two years, and under a more rational law, there has been considerable progress, and it is probable that before very long most people who want electricity will be able to get it.

Whether the supply of electricity to the model city should be in the hands of private companies, or should be undertaken by the local authorities, are questions likely to be answered in a different way by different people. Those of a sanguine temperament will embrace the latter alternative, picturing to themselves a municipal body, elected by the people, animated by the purest public spirit, and eager [illegible] the path of improvement. Others doubt how far this ideal is attainable in the present state of the [illegible] of human nature, and in the meantime would prefer [illegible] so far as may be, to private enterprise. [illegible] in favor of arrangements similar to those now in force with certain gas companies, whereby [illegible] upon a certain standard carrie with it an obligation to reduce in a proportionate degree the price charged to the public. In this way the management retain in a sufficient degree the natural stimulus to seek out and adopt improvements, whether of a scientific or of a commercial character, but at the same time they are not allowed to use their position as monopolists to put the whole money value into their pockets.

The supply of electrical energy may be either on the steady or on the alternating current system. The former is the easier to understand, as it is analogous to hydraulic power. All students of mechanics know that in the latter case the power may be treated as the product of two factors (1) the pressure, measured perhaps in pounds per square inch, and (2) the flow, measured in gallons per minute. In precisely the same way electrical power depends upon the electrical pressure measured in volts, and upon the current, measured in amperes. So far as energy is concerned it comes to the same thing whether we have one ampere at 100 volts or 100 amperes at one volt. But as the loss of power in the conducting mains depends upon the current and not upon the pressure, economy of distribution is promoted by the use of high pressures. This consideration becomes more and more important as the distance increases to which the supply is to be carried; so that economy precludes the extension of a low-pressure system over a very wide area. On the other hand two obstacles stand in the way of high pressures. Above 200 or 300 volts electricity become dangerous, and it is usually considered that the pressure brought into private houses should not much exceed 100 volts.

If the district to be dealt with is of moderate area the simplest plan is to use one pressure throughout. The Kensington and St. James' stations, now in successful operation, are upon this system. The current is generated by dynamo machines driven directly by quickly revolving engines, and is led through the streets by massive copper strips, supported at intervals by glass or porcelain, and contained in culverts under the footways. Such is the efficiency of the machinery that Mr. Crompton estimates the electrical output as 85 per cent. of the power indicated in the cylinders of the steam engines.

In the alternating current system the flow of electricity is backward and forward. For perhaps one two-hundredth of a second the motion is forward and during the next two-hundredth of a second backward, so that the complete cycle occupies one hundredth of a second. The principal, perhaps one may say the only, advantage of this system is the facility with which it lends itself to transformation. Electricity may be generated and distributed at high pressure, and at the last, or nearly the last, moment be transformed without much loss of energy into electricity of low pressure. It is as if a gallon of water at a pressure of 100 pounds to the square inch could be converted into 100 gallons at a pressure of 1 pound. In this way the security of a low pressure in the consumers' houses can be made compatible with the economy of a high pressure in the distributing mains. It is thus possible to supply at a considerable distance from the source, as is actually being done in London by the Electric Supply company, whose generating station is seven miles away, at Deptford. On the other hand it is contended that the losses in the transformers, together with the increased cost of insulation for mains at high pressure, neutralize the advantage which the alternate current system might otherwise possess.

He would be a bold man who should pronounce with confidence at the present moment upon which system the model city of the future will be lighted. It may be that both will hold their own. More probably the question may be decided upon other grounds than those connected with lighting. It is the opinion of many competent authorities that the supply of mechanical power may ultimately prove to be as important as the supply of light. If this be so, the scale can scarcely fail to turn in favor of the steady non-alternating current, which lends itself more readily to mechanical and chemical uses.

The extended employment of electricity for various purposes would remove one difficulty which at present presses heavily. The demand for light is unduly concentrated upon three or four hours of the evening. During these the station must be able to meet the simultaneous requirements of both shops and private houses. Mr. Crompton finds that on the average of the year the demand in a residential district is only about 8 per cent. of that which the plant could supply if capable (as it must be) of dealing with the hours of greatest strain. It is needless to point out that under these conditions the machinery works at great disadvantage. On the steady current system a partial remedy may be found in the use of secondary batteries, by which electrical energy is stored in a chemical form, somewhat as gas is stored in gasholders. But anything tending to equalize the consumption over a large part of the twenty four hours would greatly simplify matters, and would ultimately enable the companies to reduce their charges. Such would undoubtedly be the effect of the extensive application of electricity to the distribution of mechanical power.

The Power of the Future.

It is only a question of time when electricity will universally supersede horses, steam and gas, in all their various applications. The late remarkable discovery in electrical forces made by Nikola Tesla, described by him at the recent meeting of electricians in New York, presents new possibilities in the universal application of the most marvelous power in nature, and promises to transform all means of lighting cities. Nor is it in vain to look to it for heat, and we believe that the time is in the near future when we shall turn on the heat in our rooms by the key, as now we turn on gas at night. This will do away with at least one servant, who, in large houses during the winter is required to attend to the furnace and grate fires, without adding further to his duties. It will be also a great economy in the wear of furniture and the preservation of books and pictures. Electricity is the power of the future. *Boston Manufacturers' Gazette.*

CORRESPONDENCE.

New York Notes.

NEW YORK, August 1.— The rapid transit question is emphatically the topic of the hour. Last week I endeavored to give some idea of the involved condition in which the commissioners have succeeded in landing the whole scheme, the results of which are of such vital importance to the city of New York and its million and a half of workers. The plan of having a common track for the down town portion of the two lines has evoked only the faintest protest from the daily press, although the comments that have been made are for the most part unfavorable. The fatuity of the error that has been committed in adopting such a plan does not seem yet to have struck home either to the people or the press, but it will in time, and it is only to be hoped that the awakening will not be left to the rude shock of bitter experience. The remark of the chairman of the Rapid Transit Commission, which I quoted last week, to the effect that the Greathead system would not be used because it is specially applicable to deep tunneling, and the tunnels in New York would be as near the surface as possible, called forth a very strong letter of protest from Frank J. Sprague, the president of the Greathead Subway Tunnel company. Mr. Sprague protests in vigorous language against the proposal of the commission to forward the reports of the engineers to the mayor and common council for approval, without allowing them to be made public for criticism and comment. He also protests against the assertion that the Greathead system of tunneling is too expensive, and that a system of open cutting on Broadway would be resorted to. As MR. Sprague says, the opinion of many noted engineers who have been, and now are, connected with some of the most important engineering works, is that by the use of the Greathead shield the lower Broadway tunnel can be more rapidly, cheaply and safely constructed than in any other way. The North River tunnel, a most difficult piece of work, is being constructed with English capital subscribed on condition of the employment of the Greathead system. The same method of construction has been successfully employed on the St. Claire tunnel and under the River Thames, and is to be used on other works in London of equal magnitude to that of the Broadway tunnel.

Mr. Sprague's letter, which was a most forcible indictment of the bungling policy of the commission, caused the chairman of that worthy body to altogether lose his temper. Mr. Steinway felt very much aggrieved at being taken to task, and in a newspaper interview proceeded to contradict most of what he had said before. He denied that he had said that the Greathead tunnel would be too expensive, or that "our" roads were to be as near the surface as possible, and qualified such statements (which in a previous interview with the same reporter he was explicitly reported to have made), as the most unmitigated nonsense that he had ever heard in his life. He looks on the Greathead system as being "among the best and cheapest ways of making tunnels." How many "best and cheapest ways" the Greathead system shares the distinction with, Mr. Steinway did not state. Mr. Steinway wound up by making this handsome undertaking: "The people of this city may rest assured that this commission will exhaust every means to devise for them the most perfect system of rapid transit possible. They will not hastily adopt any scheme. They are not going to adopt finally any plan until they have had the advice of the most eminent engineers in the world—men totally detached from schemes of profit, and able by character, attainments and position to look at the problems presented from a purely scientific point of view." Mr. Sprague may be able to discern "one for himself" in the last part of this important announcement, but at any rate he has done a public service in drawing out the chairman of the commission and inducing him to correct previous reports of a very disquieting nature. One word more on rapid transit, and this to show that great minds run on parallel lines. Mr. Sprague in his letter made precisely the same suggestion that I made in my last to you, namely, that the company obtaining the franchise should be allowed to build and equip the road in its own way, of course with certain well-defined limitations, and curiously enough Mr. Steinway seems to concur in this, although all his previous utterances have led us to understand that the engineer's plans would be presented cut and dried and have to be followed to the letter.

The district attorney has selected another newspaper for a free "ad" in connection with the publication of details of the recent executions at Sing Sing. The proprietor of the *New York Herald* has been indicted for the same offense against the law that secured the indictment of the city editor of the *Daily News*. The proceedings in these cases are farcical in the extreme. The district attorney and his assistants give newspaper interviews in which they state that they believe the law to be a bad one, unconstitutional, and all the rest of it, and that it is certain to be amended; they even go so far as to suggest points that may be made by the defense to the indictment. The *Herald* of course is jubilant at being selected and publishes a column or two of matter on the subject every day, declaring that it is made the representative of American journalism, the defender of the liberty of the press and the champion of the people's rights; the honor is accepted with "confidence that the result will be the annulment of a law that should never have blotted our statute book."

The naval militia has acquitted itself admirably during the week's drilling off Fisher's Island which has just come to an end, and the officers of the White Squadron, from Rear Admiral Walker down, are loud in their praises of the smart bearing and excellent discipline of the members of the battalion. Some capital practice was made with the big guns, the firing being at floating targets while the ships were steaming four knots; the *Herald* accomplished quite a feat of journalism by transmitting by telegraph a diagram of the target giving the results of the various shots fired from the different ships.

The grand jury has been investigating the hospital and ambulance service of the city and has just made a presentment regarding the defective system of sending in calls for ambulances. The jury considers it a libel on the development of this great city that it is without a comprehensive system of signal boxes or stations scattered through the streets in large numbers from any of which an ambulance could be summoned to the prompt relief of an urgent case. It is urged that the board of police commissioners use all possible speed in selecting the most perfect system by which the entire patroling force of that department may be at all times in complete and rapid communication with the station houses, both for police purposes and for the relief of the ambulance service. When this selection shall have been made, after exhaustive competitive tests by the police department, prompt action is urged on the part of the board of estimate and apportionment in making the appropriation necessary to bring into existence this greatly needed addition to the useful functions of the city. This is a step in the right direction, and the general system of police and ambulance calls is something that is badly needed in New York. In such matters, New York, as the presentment says, is behind scores of smaller cities If the matter is carried through on the lines suggested by the grand jury, there will be an excellent opportunity for the electrical contractor.

Questions of surface traction are almost as active as the much discussed rapid transit schemes. There is now talk of another cable road on Sixth avenue. The Sixth avenue company tried to get an injunction against the Broadway company to restrain it from crossing the Sixth avenue tracks with the cable, on the plea that such a crossing—which is a matter of necessity for the Broadway road—would interfere with any cable that they might put down. The injunction was denied, and now the Sixth avenue road is asking for permission to use cable traction. The petition is put forward in the names of business men and real estate owners, but it is understood that the railroad company is in favor of using cable power and is backing up the petition, which is signed by over two hundred well-known business men who have places on Sixth avenue. A delegation from among these will appear before the sinking fund commissioners at the next meeting of the board and urge favorable consideration for the new scheme. Fourth avenue, wiser in its generation than its neighbors, scorns the clumsy mechanical devices that they are content to impose on the traveling public, and prefers the agile and independent storage battery car. The equipment of sixteen cars, idle since last January, when their accumulators were unable to overcome the high resistance offered by an injunction, is to be put in thorough working order at once. The cars have been removed to the factory of the United Electric Traction company, at Marion, N. J., to be repaired and overhauled generally. New batteries are to be provided, and the cars will probably not be in service again until late next month. The superintendent of the Madison & Fourth avenue railway says that the company will adopt the accumulator system definitely if the trial, which was broken off by legal proceedings before the specified time had expired, is satisfactory. He also said: "Of the cars that were used on our line, I have no hesitation in saying that, mechanically, they were entirely satisfactory, and by 'mechanically' I mean all their features, electrical and otherwise."

The president of the Consolidated Electric Storage company, which now owns the Brush patents, expects future business in electric traction by storage batteries to be pretty lively. The system will be immediately adopted at Washington, where the Metropolitan Street Railway com-

[illegible] cars in service at once, and in New Orleans the Carondelet street [illegible] Mr. [illegible]

tric traction by storage batteries has been prevented only by the uncertainty arising from the litigation. Electrical men will certainly be glad to see the storage battery cars have a fair chance to show what they can do. They provide the ideal system of electric traction for surface railways in cities, and if they can be made a success financially no city would be justified in allowing the use of either the cable or the trolley within its limits.

Electric railway matters excited some attention in Newark for a day or two last week. The Newark Passenger Railway company bought the line of the Rapid Transit Street Railway company for $1,000,000, and it may be mentioned in passing that the seventeen stockholders who owned the "Rapid Transit" line put into the enterprise just about a year ago exactly $200,000, so that they cleared a net profit of 400 per cent., which goes to show that electric traction systems are sometimes very profitable. A day or two after the transfer eighty of the motor men and conductors went on strike because the company that had acquired their line increased their hours of duty without increasing their pay. The cars were stopped for some time during the day, but the company soon got men to fill the places of the strikers, and although there was some disturbance the strike was very soon at an end. The amalgamated Newark Passenger Street Railway company will operate an electric railway between Newark and East Orange. In Orange, by the way, the common council is in doubt whether the streets shall continue to be lighted by electricity for the next five years, or a return be made to gas lamps. It is said that to return to gas lighting would mean a saving to the city of $7,500 a year. Surely, with Llewellyn park and all its wonders so near at hand, Orange will not discard electricity for the sake of such a trifling sum as $7,500 a year!

Last Saturday Mr. and Mrs. Edison gave a dinner at their Long Beach cottage to celebrate the victory in the incandescent lamp suit. The center piece for the table—a huge cake—was designed by an Orange caterer; it was surmounted by a trophy of incandescent lamps and a "rooster," and bore this inscription: "Victory. England—America. 1879—1891." Edison stock, by the way, in spite of the victory, has not been very strong during the past week. Yesterday 146 shares were sold at 96¾, or 3¼ per cent. below par, and the closing price was 94 bid, 97 asked.

Failures in the electrical business are the order of the day in this part of the country The sheriff has this week received an attachment for $15,000 against the Easton Electric company, late of No. 45 Broadway, in favor of Samuel Rowland, on promissory notes of the company made a year ago, and indorsed by P. Minturn Smith, the late president, and William D. Perry, vice-president. Other judgment have also been taken out against the company. The Easton Electric company was incorporated in October, 1889, with a capital stock of $1,000,000 to work the Easton system of electric lighting, which had been in use in Canada. The factory of the company was in Brooklyn. Two executions, aggregating $83,580, were received by the sheriff against the North American Underground Telegraph & Electric company, formerly of 45 Broadway, but no property could be found to levy upon. The company was formed several years ago with a capital stock of $5,000,000, to work the Johnstone system of underground conduits for electrical subways, but the system was not looked on favorably by the [illegible] Electrical Control or by the Subway company, and it was never adopted in New York. The North American company some time ago took proceedings to recover damages against the Consolidated Subway company for not using the system, but nothing came of the action, which was let drop after a good deal of [illegible]

W. H.

Pittsburg, Pa.

PITTSBURG, Pa., July [illegible] residents of Indiana, Pa., are determined to keep in the front rank. A few days ago the electors of West Indiana Borough voted on the question of lighting the town by electric light. Two weeks ago the Indiana councils decided to light their streets with [illegible] the rate of taxation in the west end is considered pretty high already [illegible] pass upon the [illegible] for the electric lights [illegible]

Francis P. Mann of the laboratory force of the Westing-

house Electric Manufacturing company left Pittsburg last week for its vacation.

The Duquesne Traction company has had its road now in operation for more than a month, and it has so far not been able to report a very brilliant success. As has been stated in this correspondence before, the company runs Pullman palace cars, equipped with Thomson-Houston motors. Experience has proved, however, since then that the equipment of one car with two motors was inadequate to the demands made on the motive power. Each of the motors was 15 horse power, and, irrespective of the fact that the cars themselves are rather heavy, the road has also a number of very heavy grades, and whenever the cars came to the bottom of one of these hills much difficulty was experienced in ascending them, especially when the cars were filled with passengers. The Thomson-Houston people have tried a number of schemes to get over this difficulty, and they have at last decided to attach another motor under each car, making the entire equipment for each car three motors. This is expected to obviate the trouble.

On last Wednesday the adjourned meeting of the stockholders of the Westinghouse Electric & Manufacturing company was held in the Westinghouse building. Mr. Westinghouse, who was himself present at the meeting, stated that the details of the reorganization of the company were being rapidly completed, and he expressed it as his opinion that everything would be ready within four weeks. B. L. W.

Minneapolis, Minn.

MINNEAPOLIS, Aug. 1.—The Western Union Telegraph company officials of New York have sprung a very agreeable surprise on the city authorities of Minneapolis, *i. e.*, that all its wires are to go under ground. An ordinance exists requiring all the telegraph and electric lighting companies to keep their wires under ground, but the authorities have never yet been able to enforce it with any degree of success. The North American Telegraph company's wires are still overhead, and also those of the Brush Electric company. The latter concern has abandoned the Dorsett conduit, which was laid over two years ago for its particular use. No reason is given for the unexpected decision thus announced by the Western Union company. It is therefore reasonable to suppose that an understanding exists between the Western Union and local officials that the other companies will be compelled to get their wires under ground at once. It is an exceedingly expensive enterprise for the Western Union, whose wires in this city are on most of the principal streets. It is a work, also, which will require considerable time before it is completed. The telephone company has made excellent progress in the work of laying its wires in underground conduits, most of them being already down. On lower Nicollet avenue, the principal retail street, and across the suspension bridge into East Minneapolis the telephone wires are still overhead, work having been delayed here by the construction of the bridge. The estimated expense of the Western Union work is $25,000. Two miles of conduit will have to be laid. The plans for the work are understood to have been completed, and a strong effort will be made to get the wires all underground before winter.

R. C. Clowry, vice president of the Western Union Telegraph company, recently dropped a few words relating to the policy of the company with reference to laying underground wires in this city, which indicated that nothing further [illegible] this end for the present at least. He holds that so long as the trolley wires of the street railway company and the wires of the North America Telegraph company and the Brush Electric company are above [illegible] of the authorities, the Western Union was scarcely under obligations to discuss a [illegible] and expensive as this would [illegible] get ready to put their wires under ground his company would be ready to consider [illegible]

[illegible] and electrical and [illegible] Thomas Lowry [illegible] Mr. [illegible] fied with the magnificent achievement of building [illegible] of [illegible] [illegible] [illegible]

PERSONAL.

Superintendent Church of the Chicago Edison company returned from an eastern vacation trip last week.

D. B Dean returned from the East last Tuesday, bringing with him several fine contracts for the Electric Merchandise company.

W. R. Mason of the Electric Merchandise company left for New York and Richmond on Wednesday to be absent ten days on a business trip connected principally with the interests of the Burton heater.

Gerald E. Fish, formerly superintendent of the Chicago Arc Light & Power company, and lately appointed superintendent of electric lighting at Little Rock, Ark., has been elected to the office of city electrician of Little Rock. Mr. Fish is to be congratulated on his rapid advancement.

NEW INCORPORATIONS.

Virginia City company, Portsmouth, Va ; capital stock, $1,000,000; water, electricity and gas works.

App'eton Edison Electric company, Appleton, Wis.; capital stock, $100,000; general electric business; A. L. Smith, Appleton, Wis.

Cambridge Electric Light & Power company, Cambridge Washington county, N. Y.; capital stock, $7,000; to supply electricity for light, heat and power.

Realty Development company, Norfolk, Va.; capita stock, $25,000; real estate and improvements, streets, bridges, water and gas works, electric works, etc.

Washington Charlottesville Construction company, Charlottesville, Va.; capital stock, $100,000; water, gas and electric works, mining, manufacturing, building, etc.

Radford Water, Light & Power company, Radford, Va.; capital stock, $1,000 000; water, electricity, gas and steam works, and machinery therefor, real estate and improvements.

Lincoln Street Railway company, Lincoln, Neb.; capital stock $2,000,000; to continue business as conducted by the Lincoln Street Railway company and the Lincoln Electric Railway company.

Van Gestel Incandescent Lamp company, Denver, Col.; capital stock, $200,000; manufacturing, buying and selling incandescent lamps, storage batteries, etc., and all kinds of electrical appliances.

Edison Light, Heat and Power company, Wheeling, W. Va.; capital stock, $500,000; to supply light, heat and power by electricity to people of Wheeling, W. Va.; N. E. Whittaker, Wheeling, W. Va.

Riverside Edison company, Riverside, Ill.; capital stock, $40,000; to erect, own and operate a plant for producing and distributing electric light and power; A. G. Barnes, Room 42, 115 Monroe street, Chicago, Ill.

Ashland & Centralia Electric Railway company; capital stock, $20 000; to conduct an electric street railway from Ashland, Schuylkill county, to Centralia, Columbia county, Pa; J. N. Minogue, Ashland, Schuylkill Co., Pa.

Spring Hill Street Railway company; capital stock, $12,000; to operate an electric street railway from O'Hara street and Madison avenue, Allegheny, to Reserve township, Allegheny county, Pa; J. H. Goehring, Pittsburg, Pa.

Fottrell Insulated Wire company, Philadelphia, Pa.; capital stock, $200,000; to manufacture insulated wire and cables, insulating materials and compounds, and electrical appliances; J. B. Colahan, Jr., 509 Drexel Bldg., Philadelphia, Pa.

Chicago Electric Manufacturing company, Chicago, Ill.; capital stock, $10,000; to make, use, sell, patent and exploit all kinds of electrical devices, appliances and machinery; Francis W. Parker, 1007 Opera House Block, Chicago, Ill.

Mt. Pleasant Electric Street Railway company; capital stock, $50,000; to operate an electric street railway from Mt. Pleasant township to Morewood in East Huntington township, Westmoreland county, Pa; Jas. S. Beacon Greensburg, Pa.

Roland Park company, Baltimore, Md,; capital stock, $1,000,000; buying, selling, leasing. mortgaging and dealing generally in lands in the state of Maryland; also to manufacture and supply gas or electric light outside the limits of Baltimore.

Norwood Park and Maine Electric Railway company, Chicago, Ill.; capital stock, $250,000; to operate and construct a line of street railway from a point in the village of Des Plaines to a point in Chicago, to be operated by electricity or other motive power; M. E. Cole, 99 Washington street, Chicago, Ill.

Boston, Mass , & Great Falls, Mont., Electric Light and Power company, Jersey City, N. J., and Boston; capital stock $150,000; to manufacture and use electricity for producing light, heat and power and construct, operate and maintain and purchase, sell and rent, mortgage and otherwise acquire electric light and power companies, lands, buildings, machinery and rights, and privileges appertaining or incidental thereto; Wallace D. Dickinson, Great Falls, Mont.

ELECTRIC LIGHT.

Another electric lighting company is being organized at Charleston, S. C., which, it is said, depends upon Philadelphia capital. It is to be known as the Economic Light & Power company, and will be capitalized at $100,000.

There is some talk of the formation of a new electric lighting company in Indianapolis.

The Hyde Park Electric Light & Power company of Chicago has increased its capital stock from $100,000 to $500,000.

The Montgomery Box company, Montgomery, Mo., has purchased a 500 National incandescent dynamo, with 40 National 32 candle power street lights.

The Chicago Edison company has installed 24 Ward arc lamps on an incandescent circuit in the drill hall of the First regiment armory on Michigan avenue, Chicago.

The Fort Wayne Electric company has lately secured large contracts in Wheeling, W. Va., Independence, Mo , and Grand Rapids, Mich. In Philadelphia it is installing its ninth central station.

A telegram from New York, August 3d, announces that fire destroyed the big plant of the Richmond Electric Light, Heat & Power company at St. George, Staten Island. The building was valued at $200,000, and was a total loss.

A special dispatch from the Brush Electric company of Minneapolis announces that the contract for the underground wire has been awarded the Standard Underground Cable company. This is the contract about which there has been so much competition during the last few months.

At the annual meeting of the stockholders of the Electric Improvement company, San Jose, Cal., it was decided to increase the capital stock to $1,000,000. Extensive improvements will be made in the works, and it is proposed to put in an all-day incandescent light service, so that there will be a continuous service night and day.

From Buffalo, N. Y., comes the statement that the conduits built for the Brush Electric Light company, but which on account of legal entanglements the company cannot use, have been attached by the sheriff of Erie county. The Brush company is the complainant, claiming $15,000 damages. The sheriff is now in possession of all the conduits and wires of the Cobb company in Buffalo. George J. Sicard, counsel for the Brush company, says that this step has been taken to obtain possession of the conduits without unnecessary delay.

The Minneapolis Electric Street Railway company has just installed a 100 light arc plant, combining the Excelsior generator and the Thomson-Houston lamps, 35 lights being used to light the central station and grounds in Minneapolis, and 65 for the suburban track and the pavilion and grounds at Lakes Harriott and Calhoun The circuit is 14 miles in length, extending along the track to these popular resorts, quite a number of the lights being put in use along the route. The current was turned on July 25th and everything worked satisfactorily.

ELECTRIC RAILWAYS.

It is reported that the Belt Line Railway company of Washington, D C., will try the storage battery system.

E. T. Lynch of New York has obtained the contract to build the North Highlands Electric road at Columbus, Ga.

An electric street railway line operated by the storage battery system is shortly to be established at Newton, Mass.

The North Avenue Railway company of Baltimore, Md., which is building an electric railroad, has increased its capital stock from $100,000 to $500,000.

On Friday of last week, "circus day," the Rochester, N. Y., Railway company is said to have carried 60,000 people in 140 cars, of which 65 were motor cars.

The Calumet Electric Railroad company of Chicago has agreed to pay 2 per cent. on its gross receipts to the city during the period of construction, being the first three years, and after that period 5 per cent.

The Citizens' Street Railroad company of Indianapolis is pushing the work of construction, expecting to have the new Irvington and North Indianapolis lines in operation by August 10th. Superintendent Steele says that twenty-two new motors have been ordered. These in addition to the sixteen now in use, will enable the company to give first-class service on all the lines.

The English electrical journals occasionally express doubts as to the progress made in this country in electric railways. The London *Electrical Engineer*, however, has evidently experienced a change of heart. In its last issue the following note appears: "Is not the St. Paul, Minneapolis, and Manitoba Railway company, which is coming before the British public this week for £1,000,000 mortgage bonds, just exactly that company on whose line (between St. Paul and Minneapolis) the trains have ceased running, owing to the vigorous opposition of the electric railway? The line spoken of is probably only of small length, but that a line is already forced to give up such a service by reason of this opposition is suggestive of troubles to come."

ELECTRIC MOTOR.

Two young business men of Des Moines, Iowa, Schiller Kurtz and A. I. Lee, have an electrically propelled boat, the Gayle Lee, with which they attract attention when they go boating on the Des Moines river. The power is obtained from secondary batteries, which operate a two horse power motor. The storage cells were furnished by the

ELECTRIC MINING.

and mill. The plant is reported an unqualified success.

contract for eight electric drills from the Poorman Mining company at Burke, Idaho. They will be put in operation at once. A complete electric plant for the operation of the

greatly increased.

TELEGRAPH.

In the lower house of the Austrian Diet the Marquis von Bacquehem, minister of commerce, recently stated that there was a prospect of the establishment in the course of the year of a direct telegraph line connecting Vienna, Munich, Paris and London.

There are 7,600 postal telegraph offices in Great Britain and Ireland. The charge for telegrams to all parts of the United Kingdom is 12 cents for the first twelve words, including the address, and one cent for every additional word. Postage stamps, such as are used on letters, are used in payment, and the sender must affix them to the message.

"It is said that the comparative activity in Western Union," says the *Daily Financial News*, "is due to the report that with the closing fiscal year, on September 30th, the directors will promptly declare an extra dividend of 1 per cent, as the statement will show something like 9½ per cent. for the 12 months, out of which the money will be taken to repair the damage to 195 Broadway caused by fire, etc."

A press dispatch from Washington says that Second Comptroller Gilkeson has approved bills of the Western Union Telegraph company amounting to $166,000 for telegraph service for the United States signal bureau at the rates established by the postmaster general. The company has notified the secretary of the treasury that it will accept payment at the rates named under protest until the question of the legality of the ruling can be judicially determined.

TRADE NEWS.

H. N. Bates & Co. of 120 Pearl street, Boston, manufacturers of traction pulley, and machinery, are about to move into quarters double the size of those now occupied. Their new catalogue will soon be ready for distribution, and it promises to excell all previous ones of their issue. They are now filling a number of large orders in Maine and Massachusetts.

The Engineering Equipment company of New York and Boston announces that its business is steadily increasing. It has just taken charge, as sole eastern selling agent, of the Boston office of the Underwood Manufacturing company, whose cotton-leather belting itwill now push in the Eastern market. This company is also pushing the Indurated Fiber pipe in New York and Boston.

H. A. Reed, manager of the Bishop Gutta Percha company, has several samples of insulating material, which have been used as a cable covering, and which have been in water for eleven years. So far as could be seen they were in as good condition as the day theywere made, being soft and pliable, showing conclusively that this material, if properly made, would stand for an untold period with ordinary usage.

Under the heading "Kind Words" the Fort Wayne Electric company has issued fac simile copies of about forty letters received by the Board of Public Works of the city of Jamestown, N. Y., in response to inquiries as to the efficiency of the Wood arc lighting system. All are highly commendatory in tone and form a flattering testimonial to the excellence of the apparatus. The Jamestown people put in the Wood system.

The Redding Electric company, 41 Federal street, Boston, has on the market an improved watchman's register. It is claimed for the Redding instrument that it is the only watchman's clock which gives a plain printed record. The record on many other clocks is made by needles which perforate the dial, making minute holes, very indistinct and hard to read. In the Redding system the register prints the number of every station in plain figures on the dial, showing the exact time of the watchman at each one. The company is also introducing the "Electrix" specialties, among which are the latest and most improved forms of gas attachments, ceiling cut-outs, single pole and double poleswitches, , sockets, etc.

A. C. Fletcher, doing business under the name of the Fletcher & Fletcher company of

interest to Herbert S. Gray, who has been connected with the business, the general public knowing him as "the other Fletcher," has been unusually prosperous, and Mr. Gray will probably continue it under the old name. Mr.

from an attack of asthma for some time and is obliged to get away from the lake winds at Cleveland, and will probably locate in Denver, taking up some form of electrical work in that city. Mr. Fletcher is an active energetic business man, and will undoubtedly succeed wherever he may locate.

The Lord Engineering

activity in the telephony

Chicago and St.

Louis offices. In addition to the two 400 horse power Armington & Sims engines now being furnished the Edison station in Chicago it has just started 250 horse [illegible] Sims in the station of the Cicero & Proviso Electric railway. This is the second electric railway now in Chicago, both of which are using Armington & Sims engines, furnished by the Pond Engineering company. It is furnishing the Murphysboro Water Works & Electric Light company an Armington & Sims engine of 120 horse power; also a complete steam plant for the Grand Ridge, Ill., Electric Light company, and one automatic engine, vertical pattern, to the Chicago office of the Edison General Electric company.

The Ball & Wood company is the sole manufacturer of the Improved Ball engine, and is now ready to deliver engines from its new shops at Elizabeth, N. J. The officers of the company are gentlemen who are well known to engine buyers, and are well posted as to the requirements of the business. They state that it will be their policy to anticipate, if possible, the requirements of the trade and with this in view they have designed and built, in addition to other types of engines, a vertical compound engine of 500 horse power for central station and railroad work, which is highly spoken of by all who have seen it. They are now prepared to furnish all types of engines, simple, tandem or cross compound, condensing or non-condensing, triple expansion, vertical or horizontal. All engines will be furnished with the governor. W. B Pearson & Co., 401 to 403 Home Insurance Building, are the Chicago agents for the Ball & Wood company.

BUSINESS.

The Creaghead Engineering company of Cincinnati is bringing out several specialties looking to the perfection of trolley line insulation, using glass as the medium. Several new forms are now being patented, and when perfected will be placed on the market.

The Chicago Electric Motor company has purchased the necessary machinery for a general repair shop in connection with its manufacturing business, and will rewind and repair armatures for railway and other motors and generators of all makes.

The Bush Revolving Store Fixture company, 24 Park place, New York, has just completed and put on the market a triple spool motor, to be run by a current of two volts and two-tenths of an ampere Instead of a commutator contact points are used. These motors are used principally on revolving store fixtures, and one motor will propel three to five tables with two cells of Edison "G" battery.

The Electrical Supply company, 104 Michigan avenue, Chicago, reports that general business is unusually large for the present season of the year. It finds that the new and commodious building is proving quite an attraction for out of town customers, as well as those in the city. Its sale of Sunbeam lamps keeps up to a phenomenal degree for the summer, which seems to indicate that they are finding much favor with consumers in general. The demand for Habirshaw wire still continues.

The C. E. M. jack-knife switch, made by the Consolidated Electric Manufacturing company, is having a large sale, and is pronounced one of the best current breakers on the market. The C. E. M. company is also doing a good business with its new key socket, and the new Davis arc cut-out switch is being shipped all over the country and Europe. Many other new and useful inventions are being pushed forward by this company, and under the new management success is assured.

The Law Telephone company, 85 John street, New York, has just issued a new and attractive pamphlet setting forth the merits of the improved Law battery, the Bailey current regulator, milliampere meter and Dubois-Raymond coil Simplicity and durability are the two principal claims made for these appliances. The book contains many flattering testimonials from well-known physicians in all parts of the country, from which the popularity of these appliances among the medical fraternity may be judged.

The Copenhagen Electric Alarm company, 92 Sycamore street, Cincinnati, is meeting with flattering success in the introduction of a new thermostat fire alarm system for buildings, which has recently been perfected. The com[illegible] Cincinnati are equipped [illegible] and are giving satisfaction. The ap[illegible] on the market a few months, but [illegible] from operators. The company [illegible] at Auburn, N. Y.

[illegible] company has [illegible] for a [illegible] wide [illegible] of [illegible] guaranteed [illegible] case of [illegible] num would give better service, requiring less labor in [illegible]

The Fort Wayne Electric company has booked orders since June 1st for 3,850 arc lamps with dynamo capacity, and 8,450 incandescents, as follows: Arcs.—United States Electric Light & Power company, Buffalo, N. Y., 120; Complete Electric Construction company, Weehawken, N. J., 80; Southern Electric Light company, Philadelphia, Pa., 60; Thomas Grimwood, Atlantic City, N. J., 160; Mutual Electric Light company, Alliance, O., 40; Detroit Electric Light & Power company, Detroit, Mich., 80; Fort Wayne Electric company, Coney Island, N. Y., 50; Inter-colonial Railway company of Canada, Moncton, N. B., 25; Citizens' Electric Light company, Pueblo, Colo., 80; Joseph P. Witherow, Middlesboro, Ky., 60; Paris Gas & Electric company, Paris, Tex., 80; Geo. W. Kelley, Philadelphia, Pa., 80; W. J. Morrison, Toronto, Ont., 15; City of Pulaski, Pulaski, Tenn., 30; J. P. Smith, Peoria Ill., 160; Louisiana Electric Light company, New Orleans, La., 600; city of Chicago, Chicago, Ill., 120; Greenwich Electric Light & Power company, Greenwich, N. Y., 60; village of Cuyahoga Falls, Cuyahoga Falls, N. Y., 50; city of Galion, Galion, O., 40; City of Wheeling, Wheeling, W. Va., 480; City of Grand Rapids, Grand Rapids, Mich., 300; isolated plants at Chicago, Ill., 600; Isolated plants at Tacoma, Wash., 120; Fremont Gas & Electric company, Fremont Neb., 50; Bessemer Machine & Foundry company, Birmingham, Ala., 75, People's Gas & Electric company, Chillicothe, Mo., 50; Municipal Construction company, Chillicothe, Ill., 60; Brush Electric company, Buffalo, N. Y., 80; People's Electric Light company, York, Pa., 60. Incandescents.—Thomas Grimwood, Atlantic City, N. J., 650; Dallas Electric Construction company, Dallas, Tex., 650; Beloit Electric Light & Power company, Beloit, Wis., 650; Monticello Electric Light company, Monticello, Ill., 650; Thomas Spencer, Cumberland, Md., 650; city of Pulaski, Pulaski Tenn., 650; Frankford avenue Merchants' Electric Light company, Philadelphia, Pa., 1,200; Moundsville Electric company, Moundsville, W. Va., 1,200; University of Michigan, Ann Arbor, Mich., 300; Citizens' Electric Light company, Pueblo, Colo., 1,200; Bessemer Machine & Foundry company, Birmingham, Ala., 650; village of Cuyahoga Falls, Cuyahoga Falls, O., 300.

ELECTRICAL PATENTS.

Issued July 28, 1891.

456,558. Electrode for Secondary Batteries. Otis C. Flick, Brooklyn, N. Y.

Claim one describes a method of making electrodes for secondary batteries, consisting in casting or placing pure metallic lead into apertures, cavities or recesses or upon the surface of a metal or alloy that is not affected injuriously by the exciting liquid of the battery, then converting the pure metallic lead into a carbonate of lead or other salt or oxide of lead, and then converting said converted pure metallic lead into lead of a spongy or granular nature while held in the cavities or apertures or upon the surface of the plate.

456,574. Span Wire Insulator. Walter S. Jarboe, William P. Seibert and John White, Allegheny, Pa.

This invention relates to what are commonly known as "span-wire insulators"—that is, to a form of insulator employed to insulate the span-wire from which the trolley wire is suspended in the overhead system of electric railways.

456,593. Regulation of Dynamos Driven by Compressed Air. Victor Popp, Paris, France.

This invention relates to a method of operating dynamo electric machines from a system of compressed air distribution, and it consists in an arrangement of the dynamo and its driving engine.

456,598. Electric Arc Lamp. Francois L Sautter, Paris, France.

This invention has for its object improvements in electric arc lamps, and relates especially to the automatic maintenance of the luminous point in the focus of the apparatus in which the lamp is placed, whether a light house, a projector or any other apparatus.

456,600. Span Wire Insulator. William P. Seibert, Allegheny, Pa.

456,610. Cable Head for Electric Wires. Upton H. Balsley, Philadelphia, Pa.

456,612. Electro Motive Force Regulator. Edward M. Bentley, Boston, Mass.

This invention has for its object the regulating of electric generators or motors, which consists in dividing them into two sources of electromotive force, and completing the circuit of each source through a variable portion of the other.

456,622. Magnetic Separator. David E. Lain, Yonkers, N. Y.

This invention relates to an improved form of magnetic separator, and contains such an arrangement of parts that the material to be separated is subjected to the action of gravity and of a centrifugal force of variable amount, which tends to remove the material from an apron or barrel on which it is carried, while the magnetic line of force from a battery of magnets inside the barrel tends to hold the magnetic part of the material against the barrel.

456,[illegible] Signal Alarm for Grain Bins. Walter C. Adams, Racine, Wis.

This invention relates to devices for elevating and transferring grain, etc., in mills, elevators and other [illegible] the object being to provide an indicator which will surely give an alarm when the discharge of [illegible] the elevator [illegible] or wagon [illegible] condition.

456,[illegible] Time-controlled Photograph Apparatus. Emil [illegible]

456,[illegible] Connector for Pipe for Electric Wires. Edward [illegible] St. Louis, Mo.

456,684. Electric Gas Lighter. Adolph Wunderlich, Cleveland, Ohio.

456,685. Automatic Electric Gas Lighter. Adolph Wunderlich, Cleveland, Ohio.

456,718. Coin Controlled Electrical Apparatus. Theodore L. Brooks, Port Byron, N. Y.

456,746. Medical Induction Coil. Henry A. Voelkner, Detroit, Mich.

456,803. Annunciator. William C. Dillman, Brooklyn, assignor to Owen Walsh, New York, N. Y.

This invention relates to improvements in that class of annunciators which are used in connection with speaking tubes. These speaking tubes are usually arranged in a building so that the tubes connecting with the various rooms will all center at a common point, usually the office, and in case a person in a distant room is desirous of speaking with the office it is necessary to give some kind of a call and to indicate which tube is to be used. The object of this invention is to produce a simple electrical device which will indicate the tube to be used.

456,804 Alternating Current Motor Michael Von Dolivo Dobrowolsky, Berlin, Germany.

This invention relates to such electric motors as are driven by a plurality of alternating currents of respective different phases. As is well known, motion is produced in the said motors in such a manner, that the alternating currents are caused to generate in a body of iron, constituting a field magnet, magnetic poles which continuously alter their position, and that an armature placed movably under the influence of the said poles is forced by the latter to partake of their motion. The improvement forming the subject of this invention consists in the particular arrangement and combination, with the motor, of the conductors serving to receive the operating currents.

456,817. Electric Circuit Changing Apparatus. Hammond V. Hayes, Boston, Mass.

This apparatus as a whole was designed as a marine telephonic outfit, and is intended for use on ships as a means of communicating orders or instructions and other necessary messages between the bridge and other parts of the ship. It is of course not restricted to such use, but is of such character and construction as to be conveniently employed under varying circumstances and conditions.

456,827. Clutch. William H. Johnson, Brooklyn, N. Y.

456,835. Electric Condenser Regulator. James McBride, Brooklyn, N. Y.

This invention has reference to apparatus for automatically controlling the supply of cold water to condensers in accordance with the quantity or pressure of the vapor which is condensed, the object being to obviate waste water, to secure a uniform vacuum and to insure that the quantity of water supplied to the condenser is always proportional to the quantity of heat or the pressure going to the condenser.

456,836. Railway Signaling Device. William Newcomb, Johnsonville, N. Y.

This invention has for its objects to provide automatic devices which are conjunctively operated by electricity and a moving locomotive or train of cars, whereby said rolling stock will be protected from collision with other trains.

456,843. Secondary Battery. Henry Pieper, Liege, Belgium.

The purpose of this invention is to increase the capacity and efficiency of the electrolytic system, and this is effected by artificially increasing the opposing initial resistance to the chemical decompositions by means of which the work is to be stored up.

Claim one is the method of increasing the capacity of primary and secondary batteries effecting their depolarization which consists in maintaining within the battery fluid gases in solution under pressure.

456,859 Electric Light Crane Charles H. Shank, Armourdale, Kan.

456,865. Show Stand. John W. Tyler, Dayton, Ohio.

456,888. System of Electrical Distribution. Morris Feilbogen, New York, N. Y.

This invention relates to an improved system of electric distribution; and it has for its objects to provide for interrupting the current of a constant electric generator or dynamo electric machine generating a constant current, so as to give the proper impulses to an industorium or a series of such devices to generate a secondary current, or a series of secondary currents to be employed in an electric light or working circuit, or a series of such circuits.

456,889 Electric Circuit Breaker for Secondary Generators. Morris Feilbogen, New York, N. Y.

456,928. Electric Hoisting Machine. George H. Reynolds, New York, N. Y.

This improved machine is adapted for operating by an electric motor, and is controlled by introducing a greater or less resistance in the electric current which drives the motor. It provides convenient means for varying the amount of resistance at will between wide limits.

456,925. Armature for Motors and Generators. Norman C. Bassett, Lynn, Mass.

This invention relates to improvements in iron clad armatures in which the armature coils, instead of passing over the periphery of the armature core, are passed through the perforations near the periphery, so as to allow the iron of the core to extend between and around said coils and form an iron periphery. The advantages of this construction in reducing the resistance of the magnetic circuit, and protecting the coils from injury are well known.

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and is **guaranteed to be waterproof, and will not deteriorate, oxidize or crack,** and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

Beware of little Expenses; a small leak will sink a great ship.—FRANKLIN.

The axiom which in Franklin's day was replete with Truth, is no less a vital law to-day. It applies as well to little ships as great ones, and to a host of other things about which you and we are more intimately interested.

It is suggestive of leaks in Insulation as well as ships.

We have regarded this so in the manufacture of Wires, and—but it matters not how well you listen to the sermon, if the precepts are not heeded and followed.

Have you used Shield Brand Moisture Proof Wire? Or have you cast aside our repeated asseverations of its merit and consigned them to the waste basket as simply another lot of trade prevarications?

"BE YE THE JUDGE."

HAVE YOU TRIED THE

ECONOMIC INCANDESCENT LAMP?

If not you are losing time and we are losing a customer. Everybody that *tries it, BUYS IT*, and everybody that buys it once, *buys it again*. Kindly inform us what voltage and style of base you use and *TRY IT AT OUR EXPENSE.*

Designed for those engaged in selling, installing or handling electric batteries, electric bells, elevators, house or hotel annunciators, burglar or fire alarms, electric gas lighting apparatus, electric heat regulating apparatus, etc. The only book of the kind published.

Incandescent Wiring Hand-Book.

By Lieut. F. B. Badt.

Third Edition, Seven Thousand Copies.

72 Pages, 42 Illustrations, Flexible Cloth Binding, Type Page 6x3 Inches. Five Tables, 12x18 Inches.

These tables give *at once* and without any calculation the size of wire required in each case for any percentage of loss.

It is a book for practical wiremen and learners, and does not require any previous knowledge of wiring. It differs in this respect from other wiring tables, or computers.

The book contains full illustrations and complete information concerning methods of running wires, location of safety devices, splices, insulation, testing for faults, wire gauges, wiring of fixtures, elevators, buildings, etc. The only book of the kind published.

Electric Transmission Hand Book.

By Lieut. F. B. Badt.

First Edition, Three Thousand Copies.

97 Pages, 22 Illustrations, and 27 Tables. Flexible Cloth Binding. Type Page 6x3 Inches.

This book contains all practical information for power producers, capitalists, agents of hydraulic and electric companies, engineers, motor inspectors and other persons interested in electric power transmission. By means of the tables anybody can find at once cost of plant for least operating expenses or for minimum first cost of installation.

The book gives all necessary information concerning [illegible] and rules for ascertaining [illegible] power of motors, driving various [illegible] machinery, as hoists, pumps, [illegible] fans etc. [illegible] and original tables give [illegible] on the subject in a [illegible] book heretofore published.

FORT WAYNE ELECTRIC CO.,

FORT WAYNE, IND.,

—MANUFACTURERS OF THE—

SLATTERY INDUCTION AND WOOD ARC SYSTEM

—OF—

ELECTRIC LIGHTING.

THE MOST PERFECT OF ANY.

For references as to the merits of these systems, inquire of the local companies, the operators, or the customers in the large cities of this country where these systems are now being used almost exclusively after other systems have been tried and thrown out—Philadelphia, New Orleans, Cincinnati, St. Louis, Kansas City, Louisville, Detroit, etc.

WE MAKE ALL STANDARD SIZES OF

INCANDESCENT LAMPS FOR THE ALTERNATING SYSTEM.

Also Arc Lamps of Standard Sizes, 2,000 c. p., 1,200 c. p. and 800 c. p.

Main Office and Factory, FORT WAYNE, IND.

Vol. IX. CHICAGO, AUGUST 15, 1891. No. 7

Bridges Operated by Electric Power.

One of the latest applications of power transmitted by electricity is in the operation of swing-bridges. There are two installations of this character in the West, and in both instances the bridges are moved easily and swiftly and readily controlled. The case of the Rush street bridge, Chicago, may be accepted as a particularly severe test, as the structure is unusually large and heavy, weighing about 800 tons. Three or four men, in charge of Bridgekeeper John F. Martin, have hitherto been constantly employed on it. The bridge is located not far from the mouth of the Chicago river, and is the medium of a very heavy teaming traffic between the North and South sides. During the navigation season vessels are passing and repassing almost constantly, and for all of the larger craft the bridge has to be turned. Mr. Martin's position is considered so important that he is under bonds to the extent of $10,000 for the satisfactory performance of his duties. He now occupies the unique position of tender of the largest draw-bridge in the world operated by electricity.

Heretofore power has been obtained from an engine and boiler perched twenty feet above the roadway of the bridge, between the main trusses. When these and the heavy gearing connected with the steam mechanism shall have been discarded, it is estimated that the saving in weight will amount to about forty tons. The bridge was operated for the first time last week, and so far the motor has worked with great success. The bridge is turned fully as rapidly as by steam, and is even under better control. A noticeable improvement is the absence of the shaking and jarring caused by the overhead engine. The absence of coal, ashes and smoke is also a great advantage, and the nuisance caused by hoisting coal up to the boiler will soon be a thing of the past, although, of course, the steam plant will not be removed until electric power has had several months' trial. The cost to the city of the electrical equipment on the bridge will be about $3,000, and it is estimated that the cost of running the plant will be less than $150 per month. It is likely that in time all of the draw-bridges in Chicago will be operated by electricity.

Rush Street bridge is 240 feet long and 59 feet wide, resting on a turn-table 48 feet in diameter. Formerly the power from the steam engine was transmitted to the turning gears by means of a vertical shaft passing down through the center of the bridge and connected with a horizontal shaft on the turn-table by means of mitered gears. This shaft has now been replaced by one continuous horizontal shaft 3½ inches in diameter, on the ends of which are small pinions which mesh into large bevel gears attached to the vertical key shafts. To get the proper direction of rotation these pinions engage with teeth on the lower face of the gear on one shaft, and on the upper face of the gear on the other. To this horizontal shaft is attached the motor, so geared as to give the desired speed. This mechanism is shown in Fig. 1. On the deck of the bridge is a little house, in which are the devices by which the bridge is controlled. Directly in front of the bridge-tender is a 10 inch hand wheel, connected with a rheostat by a link belt, while at the left hand is a lever, by which the direction of rotation is controlled.

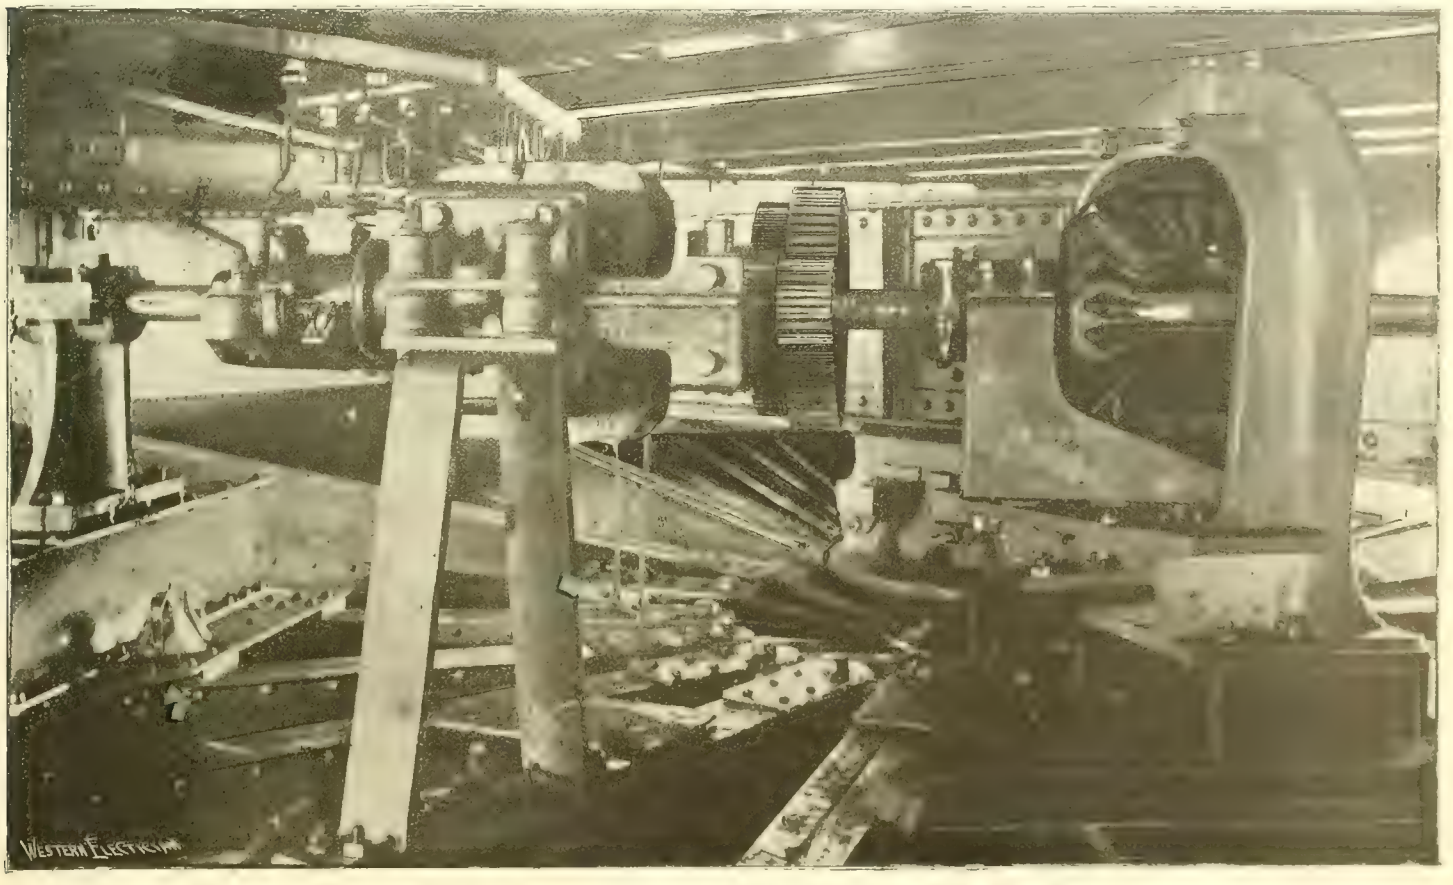

FIG. 1. BRIDGES OPERATED BY ELECTRIC POWER.

The most difficult part of the work consisted in connecting the motor with the terminals of the cables from the shore. The cables at the shore end are connected with the main current by a switch, so that they can be easily disconnected. They pass down the side of the south abutment, drop into a trench dredged in the bottom of the river, then up to the center of the bridge protection, into a channel cut in the masonry of the center pier, passing under the turn-table track up to the center of the pier. Here, firmly fastened by an [illegible] is turned true, forming a pivot holding the bridge in proper position. About ten inches from the bottom of this cone is a sheet iron disc, which fits exactly on to a shoulder turned on the cone, and to this is attached the spokes which run out radially, and form the axes for the rollers on which the bridge rests. Two straight slots are cut in this cast iron cone so as to bring the cable up back of this disc. Above this disc, and below the top, on which the bridge turns, is a space of about two feet. Here is attached a split ring, to which are screwed six T shaped insulator holders. These insulators are heavy composition bell-shaped devices. One is screwed on the branch projecting up, and the other to the branch below, the knob of the bell pointing up in each case. The top of the upper bell, and the bottom of the lower are two round angle irons, to which are screwed brass ears, which hold the copper rings, to which are attached the ends of the cables, so that these two rings make relatively the positive and negative terminals of the shore cables. Especial care and [illegible] were required to get the highest degree of insulation possible, as the current used is 500 volts by the metallic return system. To the turn-table of the bridge is attached a vertical rod, on which turn [illegible] carries a trolley, and by means of [illegible] trolley is brought against the wire [illegible] pressure. From the trolley arms two main wires are carried up, and are connected [illegible] ling device above described on the deck of the bridge.

The current is [illegible] from the [illegible] Arc Light & Power Company [illegible] South Market streets. The conductor between the station and the bridge, a distance of [illegible] wholly underground, and between the bridge and the station not one foot of the wire can be seen except at the

attachments, and as the wire is several times in excess of what will ever be required, and is placed underground, it is entirely free from any danger of derangement. The motor has been throughly tested under every circumstance, and has proved satisfactory in every respect. In starting there is a noticeable absence of the sudden jerk and the constant jar and rumble while running.

The motor and connections were put to a severe test by the violent thunder and rain storm of last Sunday. The mechanism was entirely unaffected, however, showing the excellence of the insulation.

The other draw bridge alluded to at the beginning of this article as operated by electricity is the Grand avenue bridge in Milwaukee. This is 180 feet long and 35 feet wide, weighing 200 tons. Before the introduction of electricity this bridge was operated by hand, and it could not be swung to allow a vessel to pass in less than five minutes. As the bridge had to be turned for even the smallest vessels it became essential to employ some quick-working mechanism. Previously it was turned by three, and sometimes four men, but

New Electric Road at Kankakee, Ill.

Pretty Kankakee, 56 miles south of Chicago, on the Illinois Central railway, is now the proud possessor of an electric railway system which is probably unexcelled by that of any town of similar size in the country. The city itself has a population of about 8,000, and is charmingly situated on the Kankakee river. It has a number of manufacturing establishments, and the indications are that several more will be added within a year, as the enterprising citizens of the town are determined that the advantages of cheap fuel and excellent shipping facilities shall not go unrecognized. One of the Illinois state asylums for the insane is located here, and its fine gray stone buildings, surrounded by handsome grounds, form a pleasant sight from the verandas of the Riverview, a well kept summer hotel, which is just across the river. The asylum is a very large institution, having some 1,700 patients and 200 attendants. It is conducted both on the ward and detached systems, and has the appearance of being admirably managed. The buildings are handsome and substantial and are kept spotlessly clean. They are supplied with incandescent lights and a number of arcs illuminate the grounds. Current is obtained from an isolated plant installed by the Western Electric company.

NEW ELECTRIC ROAD AT KANKAKEE, ILL.

Although the electric road had no predecessor of any sort in the way of street cars, it starts out with every prospect of success, and there is no doubt that the traffic will justify its construction. The first car was run on July 19th, and the formal opening was on the 26th, when a party of ladies and gentlemen from Chicago, headed by W. R. Mason, general manager of the Electric Merchandise company, and J. Livingston Barclay, manager of the western railway department of the Westinghouse company, inspected the line. The road is owned by the Kankakee Electric Railway company, which operates about five miles of track on Court street, Harrison avenue, East avenue, Merchant street, Greenwood avenue and Jeffries street Four Pullman cars are now running, and more will shortly be added. Each car is equipped with a twenty horse power Westinghouse motor of the four-pole single reduction type. These motors make but little noise, and work very satisfactorily. They are mounted on McGuire trucks. The line equipment was furnished by the Electric Merchandise company of Chicago, and is of excellent workmanship. W. W. Hatch had the contract for building the line, and the track work was sub let to C. E. Loss & Co. The road bed is exceptionally good, and the cars ride very easily. One branch of the line crosses the Kankakee river on a bridge 500 feet long, shown in the illustration. The distance between the floor of the bridge and the iron girders overhead is only twelve feet, but yet the trolley passes safely underneath, although bent down almost to the roof of the car. Insulators are placed on the girders to prevent leakage at the points where the conductor is pressed upward against the iron beams. Most of the overhead work is of bracket construction, although center poles are used on one of the principal streets, where there are double tracks.

The power is furnished from a Western Electric 80 horse power generator driven by a 90 horse power Payne automatic engine. Hazelton upright boilers are used. The power plant is at present located in the Kankakee electric light station, but the railway company will ultimately have a power house of its own.

Already the company is contemplating extensions to various parts of the city not yet reached by the electric lines, and before long Kankakee will possess rapid transit facilities in as great a degree as the most progressive of its citizens could desire. The Kankakee Electric Railway company is officered as follows: President, T. F. Andrews; secretary, W. M. Carpenter; treasurer, T. W. A[illegible] manager, C. H. Cobb. The road is conducted on a liberal and enterprising basis and deserves to succeed.

Burning of Wiman's Electric Light Plant at St. George, Staten Island, N.Y.

On the night of August 3d the station of the Richmond Electric Light, Heat & Power company at St. George, Staten Island, N. Y., was totally destroyed by fire. This is the plant in which Erastus Wiman is so largely interested, his son, W. Dwight Wiman, being general manager of the company. The fire, the cause of which is unknown, started shortly after 8:30 P. M. in the boiler room. Owing to a lack of water, the flames made great headway, and it was not long before the plant, with the exception of a small annex office building, was reduced to ruins, as will be readily seen from the accompanying cut showing the scene after the fire. The buildings were one-story brick structures 60 by 50 feet. In the dynamo room was apparatus to supply

BURNING OF WIMAN'S ELECTRIC LIGHT PLANT AT ST. GEORGE, N. Y.

From the Richmond plant almost the entire island was [illegible] once to rebuild, but this time nearer the shore. This move has been contemplated for some time, but the fire will hasten the building of the new plant.

[illegible] ately to the left in the view, but only partially represented in the photograph, is the site where once was located the electric fountain of the Staten Island Amusement company, [illegible] know of Yerkes' electric fountain, but few of them are aware that the electrical paraphernalia, lamps, etc., for the display was bought by Mr. Yerkes from this amusement company and transplanted to Lincoln Park, Chicago.

Chicago Electric Club.

The Chicago Electric club gave the first of a series of dinners at the club rooms Thursday evening, Aug. 6th. Twenty-two members were present. The dinner was prepared and served in excellent style and was thoroughly enjoyed. After the dinner Fred E. Degenhardt called the members to order and called upon several gentlemen for speeches. It was generally agreed that W. B. Pearson, chairman of the house committee, was entitled to the thanks of the club for the efforts he had made in arranging the entertainment, and a vote of thanks was tendered him for his efforts.

The members passed a pleasant evening in the club parlors. It was agreed that the dinners should be continued, and it is quite probable they will become one of the most attractive features of the club.

Street Railway Convention.

It is estimated that three hundred delegates will attend the tenth annual meeting of the American Street Railway association, which will be held at the Monongahela house, Pittsburg, October 21st, 22d and 23d. For exhibition purposes the committee of arrangements has chartered for the week of October 18th to 24th a [illegible] excursion boat, which will be moored at the wharf, alongside the Monongahela house. Heavy supplies can be shown on the lower deck and [illegible] The boat will be suitably decorated, and lighted in the evening, and so far as possible will be made a pleasant and profitable place for exhibition. If still more space is needed, the committee will in some way make due provision for the requirements [illegible] coming.

Single Reduction Motors for Street Railway Work.

In the accompanying cuts are shown an improved method of applying comparatively slow speed motors to street railway cars by means of single reduction gearing. Fig. 1 shows a side elevation of the truck on which the motor is mounted and Fig. 2 gives a plan view. The motor frame forms part of the field magnet frame, which is journaled upon the axle, and has projecting arms furnishing bearings for the armature of the motor. The motor consists of an outer magnetic mass or frame comparatively flat and shallow in order to adapt it to its position beneath the car-body. As seen in the figure, the armature projects well into the field coils and even through them for a short distance. Hence the field coils surround both the field magnet poles and the armature of the motor. In this equipment it is practicable to dispense with the usual counter shaft and one set of gears, and the pinion on the armature meshes directly with a gear wheel fastened on the axle. The gear wheel is split into two parts secured together by bolts. Surrounding the pinion and gear wheel is an oil casing made in halves fitted together by a gasket to prevent leakage of oil which is placed inside of the casing for the gears to run in. The motor is upheld in position by a nose piece, elastically supported from a transverse bar of the truck. The equipment is the invention of Elihu Thomson and E. W. Rice, jr.

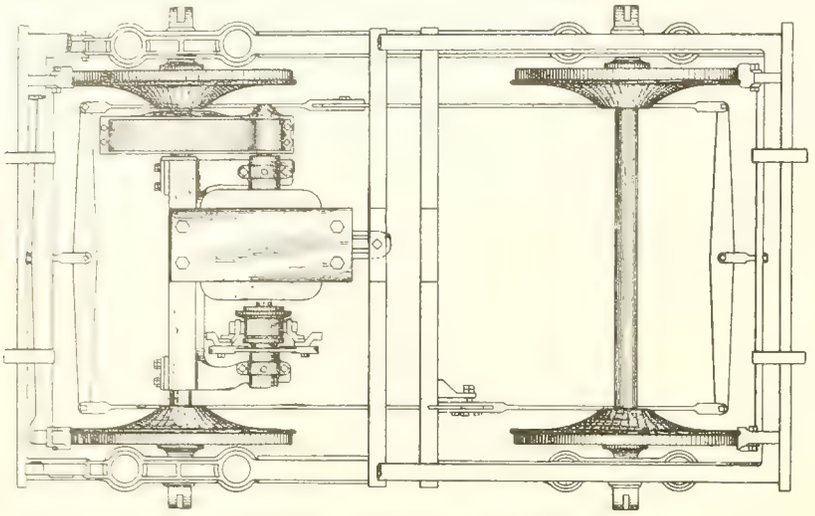

FIG. 2. SINGLE REDUCTION MOTORS FOR STREET RAILWAYS.

In both motors the armature is composed of a soft-iron strip provided with bobbins of insulated wire wrapped about the ring in notches in the edges. The armature is not only axially placed with reference to the car axle but it is mounted so as to turn without requiring any journal bearings.

It will be noticed that the armature of one of the motors is fastened to the hollow shaft which surrounds the car axle, an insulating sleeve being interposed. This sleeve may be of soft vulcanized rubber constituting a buffer or spring support as well as an insulator. In the other motor the armature is mounted directly on the car axle. In the latter case the direct driving connection is made by arms on the shaft, engaging forks, projecting from a collar on the hub of the car wheel. Spring pads of, say, soft vulcanized rubber, are interposed between the arms and the forks, the ends of the pads being protected by metal caps. The spring pads of rubber insulate the armature shaft from the forks, and at the same time furnish a yielding connection for driving. The construction of the driver permits the movement of the armature and shaft relatively to the car axle on account of the yielding nature of the sleeve. In the other motor the direct driving connection is through the mechanical means by which the armature

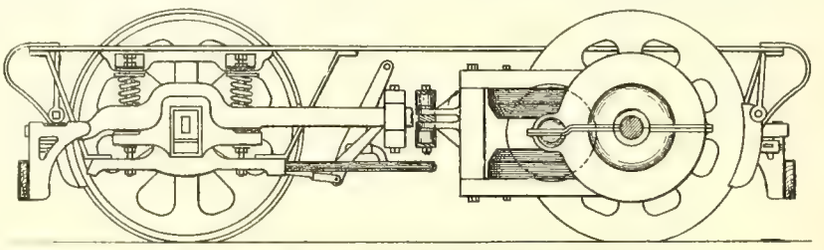

FIG. 1. SINGLE REDUCTION MOTORS FOR STREET RAILWAYS.

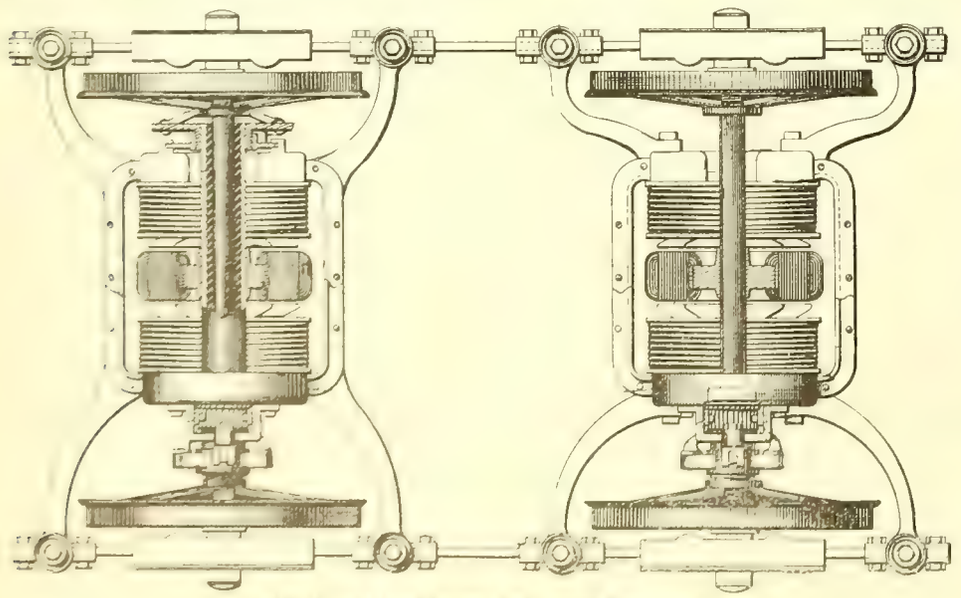
poles, each pole being constituted by the two magnets in line with each other on opposite sides of the armature. These field magnets are so arranged that the four lowermost magnets are equidistant from the lowest part of the armature, those of one polarity in front and those of the opposite side in the rear. The field magnets project from yokes, which are mounted on side bars of the truck frame, supported by the ordinary journals of the car. As shown, the side bars are secured to the journal boxes, so that they do not partake of the vertical movements of the car body. The yokes have openings in the middle for the passage of the car axle, and they are joined by connecting arms. To facilitate the placing of the field magnets in position, the frame is made in two parts. The supports by which the field magnets are mounted on the side bars are attached to the lower half of the frame. They may be made integral with the motor frame, or they may be fastened if desired.

To prevent the motion of the field magnets relatively to the armature and at the same time permit transverse movements, a collar is shown on the hollow shaft, engaging the grooved or forked ears on the yoke. A similar collar could of course be used on the car axle in the other motors whether the field magnets are or are not spring-mounted. The collar is shown as screwed on its support and may be turned to regulate the position of the field magnets relatively to the armature by adjusting said magnets lengthwise of the armature axis A pin is shown for preventing the accidental turning of the collar after an adjustment has been made.

The commutator is adjusted on the hollow shaft or on the car axle and rotates in contact with brushes. The brushes are mounted on a collar which is journaled on the hollow shaft or on the car axle, and has an arm which works in a slot in a wrist pin pivoted in the bracket on the yoke.

Gearless Motors for Street Railways.

The tendency toward gearless motors for street railway work has been particularly noticeable during the last year. Several types have been introduced and they have been generally successful in operation. Since their first appear-



The Minneapolis Cable Contract.

The closing of the contract for the underground conductors for the Minnesota Brush Electric Light company of Minneapolis was announced exclusively in the WESTERN ELECTRICIAN last week. The successful company was the Standard Underground Cable company of Pittsburg. The contract was in all probability the most extensive one of the kind ever let, and the competition was of course keen. The details of the transaction are given in another column by our Minneapolis correspondent.

F. E. Degenhardt, who secured the contract for the company, was naturally highly elated over his success, and has since been receiving congratulations from his friends and associates in business. During the last three months while the representatives of the Brush company were considering the matter Mr. Degenhardt labored unceasingly to keep the claims of his company before the Minneapolis people. The result bears the best possible evidence of his ability.

Throughout the contest Mr. Degenhardt received the hearty co-operation of J. W. Marsh, vice-president and general manager of the cable company. Both of these gentlemen are to be congratulated.

Projected Chicago Electric Roads.

The Jefferson Urban Transit company has been incorporated for the purpose of constructing an extensive West Side electric road. The company has a capital of $1,000,000. Edward D. Hosmer being president and Frederick A. Soule secretary and treasurer. It has been working quietly but effectively for about a year and already has an ordinance drawn up ready for presentation to the council when it reconvenes in September. The route it proposes to traverse is as follows: Commencing at the intersection of Canal and Monroe streets, thence west on Monroe to Morgan, north on Morgan to Fulton, west on Fulton to Western avenue, north on Western avenue to Grand avenue, northwest on Grand avenue to Armitage avenue. The promoters say that probably a storage battery or conduit system will be used.

It is reported that an electric line will be built to connect Chicago with the race track at Hawthorne. It is said that

the new road will either connect with the Ogden avenue cars or with the Cicero & Proviso electric line and the Madison street cable.

Large Wiring Contract.

General remark is excited by the imposing appearance of the new sixteen-story Monadnock and Kearsarge buildings at the corner of Dearborn and Jackson streets, Chicago. The buildings are to be lighted throughout by electricity, and the Chicago Edison company has secured the contract. They will be wired for 4,500 lights, current being supplied from the Adams street Edison station.

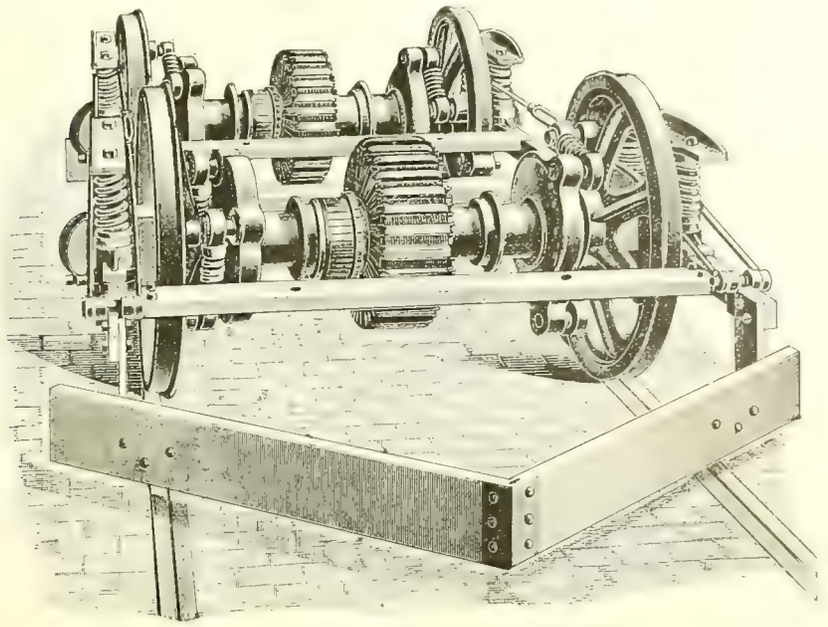


FIG. 2. GEARLESS MOTORS FOR STREET RAILWAYS.

Electric Light Plant in the New York World Building.

The home of the New York *World* is undoubtedly in the most imposing building of which the metropolis can boast. Towering above the other huge office buildings among which it stands, the gilded dome, visible even from the decks of vessels miles from the city, invariably excites curiosity. It is almost needless to say that it was Mr. Pulitzer's aim to make the *World* building the most thoroughly equipped newspaper edifice in existence, and there can be found few who would be willing to assert that he had not been successful in accomplishing his purpose.

To those interested in electrical matters there are about the building a number of interesting features. Every room is wired and piped, and the two kinds of illumination are combined in the same fixtures. In the composing room an ingenious device combines gas and electricity under one shade. The fixtures throughout the building are of special design, protruding from brass hemispheres upon the wall. Under th Park Row sidewalk and adjoining the press room is the dynamo and pump room. The illustration, which was obtained through the courtesy of E. A. Grozier of the *World*, will give the reader an excellent idea of the general arrangement of the lighting plant. Four United States Electric Light company's dynamos with a capacity of 3,500 incandescent lights, supply the current for the building. These machines also furnish the motive power for several electric motors for the proof-press and matrix table in the composing room and for other purposes.

The engines from which the lighting plant takes its power are four of the Watts-Campbell Corliss type. One pair of engines is of 300 horse power and the other pair is rated at 175 horse power. These engines can be used separately or together for the presses, dynamos, stereotyping and wetting machines. The two high-speed engines—100 horse power each—of the New York Safety Steam Power company's make are particularly intended for the dynamos, but can be utilized for the presses in an emergency.

Three large boilers generate steam for the whole establishment. Each is eighteen feet long by seven feet in diameter. They are of the horizontal tubular variety, and can develop 750 horse power. One of these boilers is always kept in reserve. All the latest and most approved appliances are found in this boiler room, including a Hoppes heater, which is placed in the flue to re-heat the exhaust steam before it goes into the heating system.

It is estimated that there are about 48 miles of wires in the Pulitzer building. All these wires come up one central shaft, especially designed for the purpose. This shaft is four feet square, and it rivals the one in the Chicago telephone exchange, containing, as it does, a veritable forest of wires. There are three big cables each made up of 12, 20 and 30 wires respectively. In addition there are over 250 wires from all sources, and others are being added almost daily. Every wire is conduited in non-combustible material, and all leave the building underground.

There are wires for the messenger call boxes in every room. The electric light system requires another wire in each apartment. The telephone system necessitates additional wires all over the building. It may be mentioned that there is, beside the public telephone, a private system for the use of the *World*, connecting all departments. There are two score or more stations with a central office. Every cable and telegraph company has its wires running up the shaft to the news desks in the dome, bringing the editors in direct communication with the news centers of America and Europe.

ELECTRIC LIGHT PLANT IN THE NEW YORK WORLD BUILDING.

The Edison Convention.

On Tuesday, Wednesday and Thursday of this week the annual convention of the Association of Edison Illuminating companies was held in the Murray Hill hotel, New York. The programme was published last week. A full report of the proceedings will be given in the WESTERN ELECTRICIAN next week.

Forging Steel by Electricity.

[illegible] of steel an inch in diameter and twelve inches long in [illegible] bar was cut into the required length, the pieces passed through the electric machine, where one end is heated, and then to a die which shapes the head on the heated end, the point being compressed into shape without heating. These were turned out by the process at the rate of six per minute. Another exhibit was the forming of an auger screw, the flat bar of iron being fastened in the machine at the ends and heated almost instantly and then twisted into the required spiral by the automatic turning of the machine. The spiral is of absolute uniformity; beyond the points of the electrical current the metal remains cool, the process occupying so short a period of time that the heat is not communicated to the ends. The hardest metals were treated as easily as the softest were by the old process, and a perfect thread shaped on the hardest tool steel as readily as upon the most pliable iron.

A little machine is devised for making spherical ball bearings, such as are used for bicycles etc. While the exhibit was in progress it was reported a cablegram was received from the Krupps, the great gun makers of Germany, in furtherance of negotiations for the rights of the invention in Germany and other countries of the European continent.

The Postal Telegraph.

The subject of placing the telegraph service under control of the postoffice department receives from a Washington correspondent the following attention in a review of the work of the present administration: "The postmaster-general's tireless advocacy of a limited postal telegraph was even more daring than his attack upon the lottery, and for several reasons. It was not an attack upon the telegraph company, pure and simple. It was merely a proposition to fit the two great machines of the telegraph company and the free-delivery service of the postoffice department into each other, so that each should help the other, thus making the use of the telegraph cheaper, and bringing it within the reach of ten or twenty millions of people instead of but one million. That is, as the postmaster-general believes, while it would offer that great benefit to the people, it would also not interfere with the vested rights of any telegraph company, a thing which he believes no patriotic person has a right to do. It might even add to the revenues of the telegraph companies, he believes, but if it did the telegraph companies would be earning their dividends not upon watered stock, but for work actually performed for millions of the people; but the telegraph company had an excellent chance to misrepresent him in this, and an immense special interest had a good chance to antagonize him. This it did not fail to do. Here again the attacks upon his financial as well as his public and personal credit were carried on with ever-increasing virulence, but they had no effect, simply because they could not have any.

"The telegraph people have taken no pains to conceal the fact that a real fight for postal telegraph would [illegible] until the last session of congress, though the semblance of a fight has been going on for the last twenty-five or thirty years. A favorable report was unanimously made by the senate committee in support of the postmaster-general's bill; a favorable report from the house committee was defeated only by one vote, and that after a series of desperate skirmishes, which at all times were sure to result in the postmaster-general's favor."

Boston capitalists are reported as intending to build an electric road in Hillsboro, Tex.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title, but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago Postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity, or any of its practical applications, is cordially invited, and the co operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—*the only general electrical paper published in the West*—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring Western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be promptly furnished on application.

financial success. This is indicated by the complaints of

as it is styled in England. In one case, indeed, the directors of another company assert that a loss of over 250,000 passengers is directly attributable to the new electric line, which has become very popular. The underground road appears to have opened the eyes of the British public to the advantages of electric railways, and it is probable that progress in this line will hereafter be more rapid in Great Britain. The City and South London railway was carefully designed, and it deserves the success it has achieved. It has many admirable features that may be studied with advantage by the Rapid Transit Commission of New York, for instance.

IN this issue an article on "Arc Lighting and Hazards" by George P. Low of San Francisco is presented. The subject is considered from the standpoint of the insurance companies. Mr. Low believes that with proper construction work the danger of fire from electric wires is far less than from any other system of artificial illumination. This position is sustained by the experience of those who have taken advantage of the improved methods of construction. The popularity of the system has been greatly advanced by the willingness of the electric companies to make use of all improvements in the art.

JOSEPH PULITZER has erected an enduring monument to his indomitable energy in the magnificent *World* building in New York. The structure is fitted up in a manner commensurate with its imposing appearance, and the electric plant, illustrated in this issue, is not the least interesting portion of the equipment. The statement that the building contains 48 miles of electric wire shows that the installation ranks among the largest of the isolated plants in the office buildings of the country. Undoubtedly the *World* establishment has the largest electrical equipment of any newspaper in the world.

THERE is a good deal of interest manifested in the controversy over the cause of the destruction of the big balloon at Chicago recently. It was stated at the time that the balloon was struck by lightning and for a time nothing was thought of the matter, but since then it has been charged that it was destroyed by one of the men in charge. The balloon was not struck by lightning, nor was it destroyed maliciously if the statements of an eye witness and one who was personally interested in the success of the enterprise are to be credited. The explanation offered is that the balloon was improperly secured at the time the big storm came up. It flapped about at the mercy of the wind, and pounded against the sharp corner of a post. After a time it wore a hole in the cover and the gas was forced out. When the balloon was turned over by the wind the hole was in such a position that the jet of gas in escaping was forced directly to an arc lamp, igniting the gas, and resulting in the explosion. This is the explanation of one of the men most deeply interested in the enterprise. He said the balloon had been too hastily constructed and the necessary precautions to secure it had not been observed. The greatest mistake appears to have been made in filling the balloon with illuminating gas.

THERE is a reckless disregard for accuracy manifested by sensational metropolitan dailies that leads ordinary observers to doubt everything that appears in the newspapers. The electrical interests have more than once had reason to complain of this failing. The wholesale invention of falsehood that appeared to rule the daily papers of the metropolis during the early days of the crusade against overhead wires caused no end of trouble to the electric companies. There are still frequent evidences of the inclination of newspapers to sacrifice the truth for sensationalism. The latest exhibition of this kind is found in the New York *Press*, which evidently considered that it was saying a very bright thing when it printed the following paragraph: "Several hundred experts of electricity might be found to-day who are willing to swear that 400 volts of electricity are not sufficient to kill a human being, but Henry Bartels, the athletic young German bartender for Theodore Feldstein of Grand street, is dead just the

The electric companies contended at the time of the accident that there was no current passing through the motor [illegible] to have received the shock, and so positive were their statements that many of the "funny" men took the matter up and proceeded to grind out stock jokes on the subject. The official autopsy, however, put a different construction on the accident. In the same issue of the *Press* from which the clipping already [illegible] on the body of Henry [illegible] dead Wednesday night in Feldstein's saloon, No. 226 Grand street. Dr. Conway decided that death was caused by uræmic convulsions, and that electric shock had nothing to do with it. Dr. Conway said that all the usual symptoms noted in cases of death by electric shock were absent."

This is not the first time, and in all probability not the last, in which the newspapers wrongfully charged fatalities to the electric current. Yet irresponsible scribblers, who disgrace their profession, persist in attributing everything to electricity about which there is any possibility of doubt.

AN English electrical engineer who is visiting in this country was interviewed at Chicago last week on the relative advancement of electrical enterprises in this country and in England. The comparison he drew was favorable to this country though by no means discreditable to the English electricians. It was the people at large, he said, who failed to take advantage of the progress made in electrical matters. "The public has been slow," he added, "to recognize in electricity anything but a force with which imaginative inventors and cranks could experiment in laboratories and lecture rooms."

This is indeed a most lamentable state of affairs, and it is not to be wondered that little progress has been made in the general application of electricity in the face of this ignorance. The successful operation of the underground railway in London by electricity has awakened the people to a certain degree to the practicability of electrical machinery. It is believed that the subway has done more in a few months than years of lecturing to prepare the minds of the people for the utilization of electricity in other ways. This gentleman has evidently a better idea of the application of electricity to the operation of heavy machinery than some of his "learned" brothers who have visited this country. He says: "It will not be long before companies will be ready to use rock drills, mining pumps, drilling machines, ship cranes, portable cranes, and other kinds of machinery operated by electricity. Electricity has been perfectly applied to all machinery of this kind for some time, but the public was afraid to take hold of it."

In this country where a more progressive spirit obtains all of these advantages have been recognized and the people have not been slow to make use of them, but in conservative England they are just now being convinced against their wills.

AN event of much interest to all electricians in Chicago took place last week, when the large Rush street drawbridge over the Chicago river was turned for the first time by electricity. This is undoubtedly the largest swing-bridge in the world fitted up for operation by electric power. Indeed, it is probable that all the bridges of whatever size turned in this manner could be counted on the fingers of one hand.

As yet the electric system may be said to be on trial, so far as the Rush street bridge is concerned, as it has not yet been officially accepted by the city authorities. But so far it has worked to the entire satisfaction of all concerned, and nothing but expressions of admiration have been heard from all who have examined it. The motor turns the bridge easily and quickly and is readily controlled. All the mechanism is under the floor of the bridge, which obviates the tremor and vibration formerly caused by the engine, which was located on the level of the top of the bridge trusses, 20 feet above the roadway. With the bridge either light or crowded with vehicles the motor has so far never failed to respond to any demand made upon it. Neither was it affected by the severe electric storm of last Sunday. In the case of the Milwaukee bridge electricity has been successfully used for two months.

The trolley devices above the pedestal of the bridge, described on another page, are very interesting. Some persons have the idea that a slack cable is used in installations of this character, but as it may be necessary for the bridge to be turned an indefinite number of times in one direction this idea would be impracticable. Instead Mr. Nichols, the engineer in charge, devised the circular double trolley arrangement alluded to. By this means the bridge can be turned freely in either direction without the slightest embarrassment from the conductors, both trolley-wheels pressing firmly against the wires at all times. Current is taken from an underground cable, coming up through the pier of masonry in mid-stream.

As may be imagined great care had to be taken with the insulation. Everything points to the complete success of the installation, and it seems altogether likely that the Rush streetbridge will but prove the pioneer in the method of operating large bridges of this character. Many of the features of the two plants described in this issue are entirely new and reflect much credit on Mr. Nichols' engineering ability.

Electrically Driven Ship's Winch.

In the accompanying cuts is shown a new form of electrically driven ship's winch recently placed upon the English market by R. Bolton & Co. of London. In this device it is said the object is to secure a great range of speed in order to adapt a constant potential current to the varying loads. Figs 1 and 2 show a plan and elevation of the

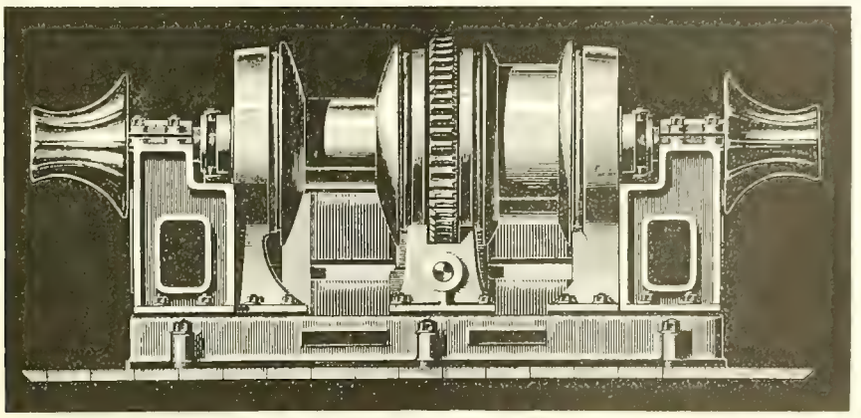

FIG. 1. ELECTRICALLY DRIVEN SHIP'S WINCH.

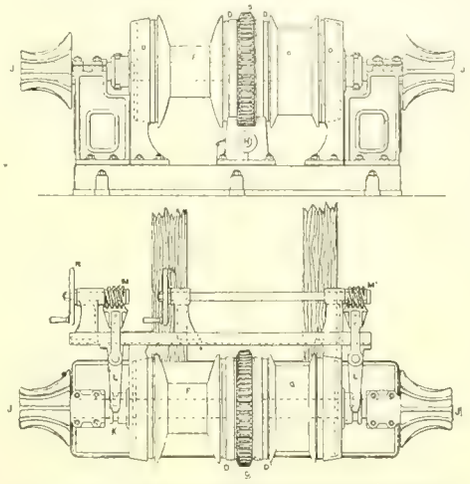
principle applied to a ship's winch, and Figs. 3 and 4 are explanatory drawings. There are two winding-drums, *F* and *G*, in line with each other and independent of each other. They may be of the same or of different diameters. Only one rope is used; the ends are wound in the same direction round the two drums, and pass up over two idle pulleys in the same pulley block, and the loop thus formed passes round the pulley supporting the weight to be lifted. The motion of the armature shaft is transmitted through a worm on the shaft *H* to the central worm wheel *C*. The friction cones *D* D^1 are attached to either side of the worm wheel, and corresponding external cones are formed in the winding drums *F G*.

These winding barrels are loose on the main shaft, but can be brought independently into frictional grip with the wheel *C* by means of the hand wheels $N N^1$, worms $M M^1$ and forked levers $L L^1$, which fit in the grooves *K* of the bosses of the barrels. Motion can thus be transmitted at will to either or both of the warping barrels *J*. There are also two fixed brake rings $O O^1$, into whose inner surfaces the corresponding rings on the drums *F G* take when the hand wheels $N N^1$ are turned in the opposite direction. The greatest lifting speed is when both barrels are attached to the wheel *C*; reduced speeds are obtained by having one drum only geared with the wheel *C*, and the other one braked. During descent either wheel may be braked or neither braked. This principle is of course equally applicable to derricks, portable jib cranes and traveling cranes. The cuts are reproduced from the *Engineering Review*, London.

A London Electrician's Opinion on Electrical Advancement in England.

James Fairfax, a London electrician, who is visiting Chicago, talked quite freely concerning electrical affairs in England, to a representative of a local daily. He said: "The people in the United States are educated far in advance of the English people in regard to the various uses of electricity. "It's not the fault of the electricians—they are well informed on all the latest inventions—but the trouble is with the people, who are slow to take hold of a new thing. Americans will give a new invention general use much quicker than will the English. As an illustration of the extent to which electric locomotion is taking hold in America, I am told that motors are being turned out of four large shops, employing in all something like 2,000 men. And the motors are being turned out as fast as they can be made. Now, the manufacture of motors and electric appliances in England will not begin to compare with that.

"The opening of the electric subway in London exceeds everything else of importance. It was put in operation last December. Although the engineers recognized at the time the full importance of the opening of the subway, they did not dream that it would make so deep an impression on the public mind. So far as the engineers are concerned, there is nothing new in what has been done in London; but, as engineers, we are simply servants of the investing public, and the public has been slow until now to recognize in electricity anything but a force with which imaginative inventors and cranks could experiment in laboratories and lecture rooms. The English people heretofore had no idea generally of the practicability of electrical machinery. But the application of electric power for the purposes of practical engineering has received a wonderful impetus since the opening of the electric subway. The great fact of the day in England is the conveyance of a million or more passengers through the London electric subway. The impression this has made upon the minds of the educated public who are not scientifically informed has been of great advantage to the electricians and engineers. The subway has done more in a few months than years of lecturing to prepare the minds of the people for the utilization of electricity in other ways. It will not be long before companies will be ready to use rock drills mining pumps, drilling machines, ship cranes, portable cranes, and other kinds of machinery operated by electricity.



FIGS. 3 AND 4. ELECTRICALLY DRIVEN SHIP'S WINCH.

Electricity has been perfectly applied to all this machinery for some time, but the public was afraid to take hold of it."

Frankfort Electrical Exhibition.

Herr Von Stephan, imperial postal secretary of Germany, has accepted the presidency of the international electro-technical congress, which will be held in Frankfort-on-the-Main, September 7th to 12th, in connection with the electrical exhibition. Delegates will be present from all European countries and the United States.

Consul General Mason has made a report on the electrical exhibition at Frankfort to the state department at

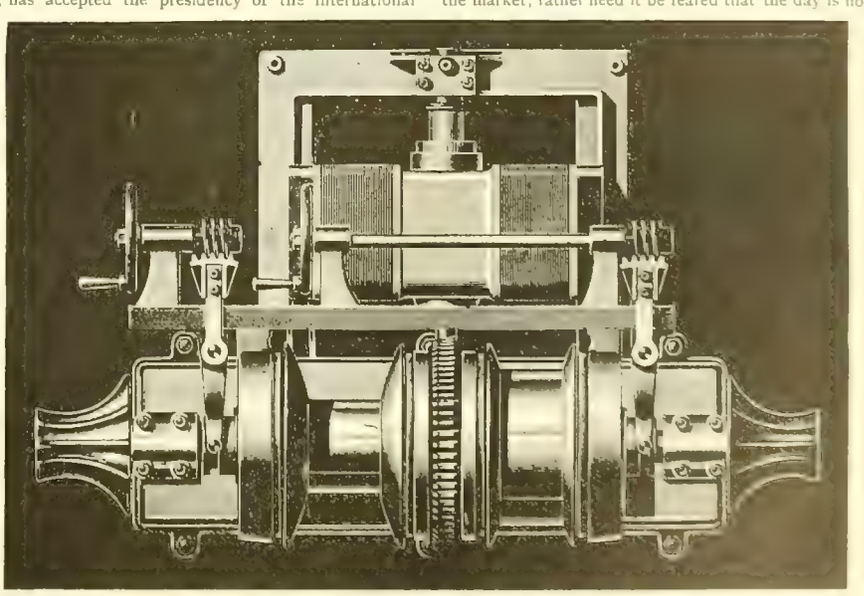


FIG. 2. ELECTRICALLY DRIVEN SHIP'S WINCH.

portant characteristic—it all means something. Nearly

London's Electric Lights.

R. P. Sellon read a paper on the progress of electric lighting in London before the Institution of Electrical Engineers. He said the progress of electric lighting in London was largely affected by the electric lighting act of 1888, which hampered the industry of electric lighting by its stringent conditions. A clause in this act gave the local authority the option of purchasing the whole of the plant of any electric lighting company at the end of 21 years at its market value. The electric lighting act of 1888 extended the period to 42 years, and provided that no provisional order should be granted except with the consent of the local authority. During the past three years electric lighting has become well established in London. Nine private electric supply companies and one local authority, the St. Pancras Vestry, are now supplying electricity in London, the aggregate capital of these companies being over £3,000,000. The equivalent of more than half a million incandescent lamps of 8 candle power are distributed over London, and more than 100 miles of conductors are laid in the streets. The Metropolitan Electric Supply company is now supplying 60,000 incandescent lamps, as against 14,000 in December last. The St. James and Pall Mall Electric Light company supplies 30,000 lamps as against 12,000 lamps last September. The Westminster Electric Supply corporation supplies 38,000 lamps, having more than trebled its production in the past five months. In these three companies the high-pressure, the low-pressure, and the accumulator systems are represented. Mr. Sellon commented on the contract between the Commissioners of Sewers of the city of London and the Brush company. In 1883 the Brush company had lighted some of the streets by arc lamps, but this was afterward abandoned at the request of the city commissioners. The present contract with the Brush company involves the abandonment of all other illuminants in favor of the electric light, and was the first instance in Great Britain of a public authority having adopted this course. Arc lamps are to be placed in the main thoroughfares, and incandescent lamps in the side streets. The advantages of the electric light as a means of protecting property were also described. The cost of lighting houses might be estimated to be greater by one-half than that of gas on the basis of 7d. per Board of Trade unit, but electricity afforded greater comfort, cleanliness, and a purer atmosphere.

What the Copper Men Think.

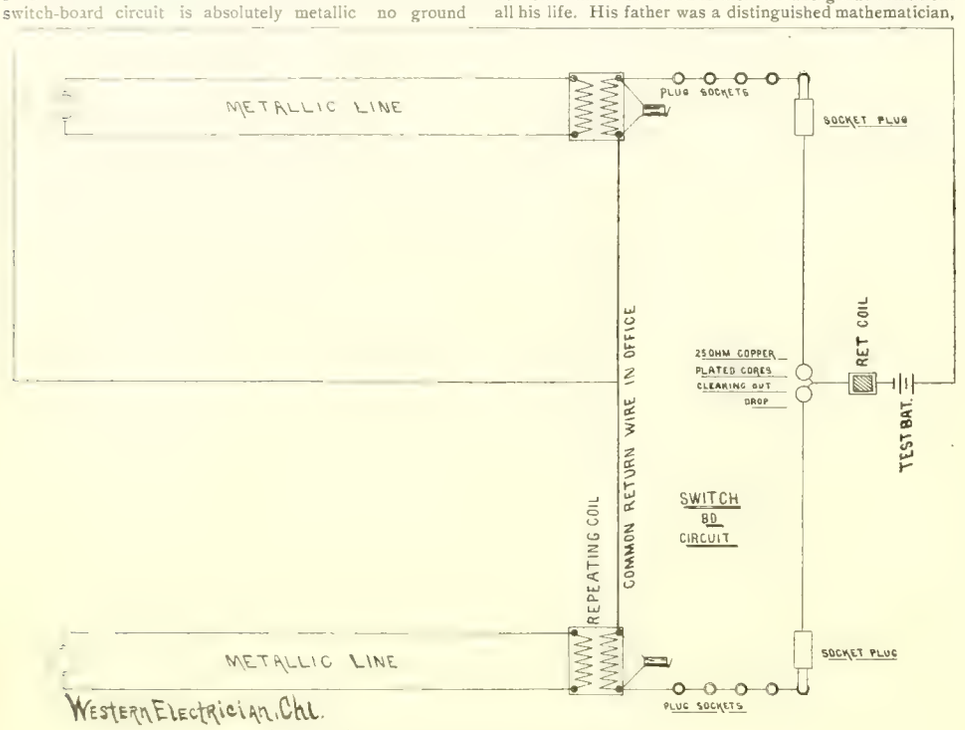
Evidently in no part of the land is the question of the great and increasing need of electricity of equal interest to what it is here, for the more extensively it is used the greater will be the prosperity of the copper country. If the new methods of lighting, heating and propelling machinery are as promising as they appear to be, the demand for copper must necessarily be very great, and production will find it hard to keep up with consumption. We have no fears that copper will ever again be a drug in the market; rather need it be feared that the day is not far distant when it will be difficult to supply the rapidly increasing demand.

A stock company has been organized to construct an electric light plant at Quanah, Texas.

O'Connell's Metallic Telephone Exchange System.

An important question among telephone men is how to simplify the switching apparatus on large multiple switch-boards. J. J. O'Connell, electrical engineer of the Chicago Telephone company, believes that the repeating coil must play an important part in accomplishing this result and that with a coil of 100 per cent. efficiency, or even 95 per cent. efficiency, a multiple switch-board for metallic or ground circuits may be made more simple in construction and at less than one-half of the cost of the present system. This system is especially designed for service in those districts where previous telephone systems have failed, owing to the disturbing effects of electric light and electric railroad currents.

The new system differs from the old in the application of a repeating coil for each line, whether single or metallic, and in the substitution of single for double cords and plugs for the connection of two subscribers' lines. The switch-board circuit is absolutely metallic no ground connection being necessary, even on the operator's or test battery circuits.



O'CONNELL'S METALLIC TELEPHONE EXCHANGE SYSTEM.

A bunched common return connects one side of all the repeating coils, or, in other words, each wire has its own return, so that no induction takes place between the inside exchange wires. The subscribers' annunciators are thrown by induced current from the repeating coil and are shunted out when connection is made on their lines, so that only the clearing-out annunciator can be thrown. A glance at the cut which is self explanatory, will give the reader a general idea of the working of the system.

Electric Heating.

In the course of an editorial on "Electric Heaters on Railroads," *Age of Steel* says: "The time honored stove, dependent on the prompt service and close attention of [illegible] with a biography [illegible] and [illegible] senses, [illegible] and [illegible] table as a [illegible] and the indefatigable [illegible] which is broken [illegible] the [illegible] property [illegible] [illegible] [illegible]

Arc Lighting and Hazards.[1]

By George P. Low.

With the advent of the incandescent electric lamp the fire underwriter believed he saw the dawning of the day when the hazard attending the production and use of artificial light would be greatly reduced, if not entirely eliminated. The idea of a minute thread-like substance, completely encased in glass and maintained at an intense luminosity with no application of external heat, without recourse to the use of inflammable or explosive oils and gases, and without open flame, at once impressed its utility upon his mind, and nearly all pronounced the new light to be simply perfection Though this first impression is now verified, it was not long before it became discredited, and with the comparatively great number of fires that occurred in the early days of incandescent lighting the fire underwriter was not slow in appreciating the fact, for the time forgotten, that artificial light, no matter what its form, can be produced at present only through agencies that are convertible into heat, for human ingenuity has not yet devised a commercially successful light without accompanying heat. In all existing methods of illumination heat is produced that it may give light, and wherever heat may occur there the fire underwriter recognizes a source of danger and at once sets about to eliminate the hazard, or to devise means that will reduce it to a minimum. It is hard to understand why insurance interests and not municipalities should have been called upon to enforce requirements that would effect the safe installation of electric circuits. Probably it is because the underwriter is quick to perceive a danger and equally ready to avert it, but be this as it may, and aside from the laudable efforts of a few of the leading electrical concerns, the only endeavors made to restrict the dangers in question have been put forth by insurance people. City governments have enforced fire ordinances and sanitary and health laws, but, singularly enough, they have done virtually nothing toward enacting electrical laws, even though they are equally important to the public safety. All this has fallen to the fire underwriters, and from ocean to ocean their requirements are looked to as authority.

It is admitted that insurance people have made mistakes in the efforts they have made, in partial proof of which it is only necessary to refer to the action of a prominent eastern board in adopting an asbestos fiber or a covering of cotton soaked in lead paint as the standard insulation, simply because it would not burn. This covering is yet known as underwriter's insulation, though in electrical circles it is facetiously termed "undertaker's wire," and but a few brief experiments were necessary to prove its unreliability for general use. Considering the fact that the board in question was reaching out into a new field explored as yet by no one, the mistake was natural, and is easily pardoned. One can have no appreciation of the magnitude of the task of framing requirements to meet any or all cases until he has tried it, and the longer he works the stronger will grow the conviction that it is impossible to draft a set of rules that shall cover even every ordinary case that may arise. Some application of electricity has worked itself into every branch of industry, and the conditions under which the electric current is used are, therefore, as diversified as the channels of human existence Different surroundings may exert widely different effects upon electric apparatus which may in turn give rise to various troubles.

With the exception of a new system of alternating current arc lighting, all systems of arc lighting are operated by continuous currents, and from their very nature continuous currents carry a hazard unknown to alternating currents. I refer to what is known as electrolysis or electrolytic action, which is most easily described by referring to an electro-plating bath. Take silver plating, for instance. A sheet of silver is connected to the positive pole of a suitable battery, such as a storage battery, and is then immersed in a solution of silver called the electrolyte. The article to be plated is connected to the negative pole of the battery, when through a peculiar electro-chemical action particles of silver are taken from the anode—as the silver sheet connected to the positive po'e is called—and deposited upon the cathode or the article to be plated. There is, in fact, a constant taking away of metal from the anode, and an equally great deposition of it upon the cathode. It is evident, therefore, that the anode must gradually wear away until it is finally consumed, in which case its entire volume will be transferred through the e'ectrolyte and distributed over the surface of the article to be plated. Accurately speaking, there is not a transfer of solid particles of metal, but what does occur amounts to the same thing, hence for the purposes of this paper the transfer of metal through an electrolyte may be considered as actual. Let us see now what figure electrolysis cuts in creating a hazard from fire. Take, for instance, a small store that is lighted with four arc lights. The wires enter through an awning and are separated the regulation ten inches. There being four lamps within the store, the potential difference of the wires at the point of entrance is consequently 200 volts. The insulation covering the wires, though sufficient for all purposes in dry weather, is not water proof, and the wire is not protected from the awning by water-proof tubes of glass or hard rubber. A shower of rain comes up, the awning and of course the wires become wet, and does not it occur to you that a plating bath, as complete as any ever devised, exists there on the awning? One of the wires is the positive pole or anode, equivalent to that of a 200 volt dynamo. The other wire forms the negative pole or cathode, and between them is the moisture on the boards or cloth of the awning which forms the electrolyte. For every hour during which the lamps burn a definite amount of copper is taken from the positive wire, transmitted thence electro-chemically through the poor insulation of the wire—insulation in name only—and the wet awning, and is deposited upon the negative pole. The copper is merely carried along with the current as it leaks through the conducting medium of moisture. True, the amount so carried across is extremely small, so small indeed that it may take years to make a visible effect upon the positive wire, but the time will surely come when the anodal wire will be so reduced in size that the current it must carry will maintain it sometimes at a white heat, then finally it will break and an arc will be maintained across the terminals. The hazard of a red hot wire resting against woodwork is too obvious to require more than merest mention, but in an electric arc is found the most intense artificial heat, in which many of the most refractory substances readily yield. The hazards attending their accidental existence and maintained is inestimably great; indeed, the many "awning fires" from electric lights that occurred until comparatively recently with alarming frequency were all directly attributable to unlooked for heating or arcing due to electrolysis. It took years of experience to learn the nature of this trouble, and now it may be entirely obviated by devoting proper care to the insulating and running of conducting wires

Electrolysis may occur, as I have said before, in all continuous current circuits, whether in arc, in incandescent or in power systems. It is most far-reaching in its action, and if you will recall the illustration given in explaining the personal hazard from arc circuits, where a fireman was supposed to have received a 250 volt shock through a "ground," on the circuit a mile away, I shall find pleasure in showing you another of the dangers of "grounded" circuits. We will presume, as in the example referred to, that an arc circuit of fifty lights is grounded at a point near the tenth lamp, and that at the point beyond the fifteenth lamp the wire passes unprotected through an outer brick wall Different gas, water and soil pipes are against the wall, which renders it an excellent ground during the wet season. Is it not plain then that the wire passing through the wall becomes as one pole of a 250 volt dynamo—the positive pole, for instance, while the metal piping referred to becomes the negative pole through the ground existing at the tenth lamp and that the moist brick wall forms the electrolyte? It is immaterial whether the ground at the tenth lamp be ten inches or ten miles distant, the positive wire will be slowly worn away until finally it parts, an arc is formed, and another possibility of a conflagration exists. Frequently I have met electric lighting men who in opposing the suggestion of better protection to wires run in places liable to dampness have retorted that "the wires have been the way they are for three years and if they will ever give trouble they would have done so in that time." Here let me offer a word to my electric lighting friends. The competent insurance inspector for electric lighting, in addition to the knowledge gained from his own researches and labors in the electrical field, holds a position that gives him a personal acquaintance with each and every electrician of note in his section of the country. He periodically visits each and every plant he avails himself of the opportunity to familiarize himself with all manner of dynamo electric machinery and accessory apparatus, and above all he adds to his stock of knowledge by bits of priceless information garnered from the experience of every electrical concern in his territory. Whether that experience be profitable or disastrous, the insurance inspector is one of the few who learns its moral, and the fire underwriter is the one who gratuitously extends this information, so carefully gathered, to all who have use for it. Our friend whose installation is defective, yet who has had no trouble for three years and who argues therefore that the occurrence of a fire from his circuits is an impossibility, falls into a fatal error from which he must some day extricate himself as best he may. I have seen wires originally half as large as a lead pencil reduced to one third or one-quarter of their cross section, and even severed altogether by electrolytic action. Other wires which were originally between one-sixteenth and one-eighth of an inch in diameter, I have seen reduced to the diameter of a thread, others to that of a hair, others completely worn away and the severed ends reduced to needle-like points, others to needle-like points from which globu'es of copper depended showing that an arc had existed, still other cases where the wood-work around the globule-tipped terminals had been burned for a radius of twenty inches or more, proving conclusively that electrolysis, the incendiary, had started its work well. In one of the last named cases the wires merely rested against plaster, and the origin of the fire is only traceable to—what do you suppose? Simply to the moisture absorbed by the plaster from the air, to the use of a non-moisture proof insulation and to electrolysis. Some may contend that this wearing away is simply corrosion or verdigris. If such is the case, why is it that only one wire is reduced in size, why is it that that wire is always the positive, and why is it that alternating circuits are not so affected? It may occur to some that water, universally esteemed as the natural enemy of fire, indirectly becomes its origin through electrolysis. For the time this may appear singular, but not more so than in a number of cases familiar to all fire underwriters in which water causes spontaneous combustion. In unslaked lime, all that is needed to raise it to a temperature sufficient to ignite wood is the application of a sufficient quantity of water. The moral is, then, keep water away from unslaked lime. If two bare wires, separated say two inches, run parallel through a piece of dry wood, if the wires carry sufficient potential, all that is necessary to ignite the wood is to wet it. Apply the same moral: Keep moisture away from the wires and the danger is effectually averted. Indeed no rule is more conducive to safety in installing all electric circuits than that of avoiding places where dampness or moisture may possibly exist. A well-known local electrician, fully appreciating the importance of this rule, recently expressed an impromptu opinion that, electrically speaking, "everything that is waterproof is fireproof." Though not literally true the saying is worth remembering.

Before leaving the subject of constant current circuits it may be well to mention a few pernicious practices which are yet prevalent and which should be discouraged by

common wire, called for convenience the negative pole.

group of lamps be introduced in series into an arc circuit

we have what is commonly, though erroneously, called a multiple-series of incandescent lamps. The object of the multiple-series system is to furnish incandescent lights from arc circuits where incandescent circuits proper do not exist, and there are several reasons why the system is extra hazardous. In the first place the public is educated to believe that an incandescent lamp, merely from the fact that it is such, is perfectly safe. The property owner sees the multiple series incandescent lamp, believes in its harmlessness, handles it with the carelessness or impunity of ignorance, and some day after he has been brought back to life by the vigorous administration of restoratives, or perhaps during a conversation with the fire marshal upon the mysterious cause of the fire that cleaned him out, he may learn that an incandescent lamp which burns on a 3,000 volt arc circuit is not perfectly harmless. Every respect is paid to an arc lamp. No one who is not familiar with it cares to even approach it, yet each multiple series incandescent lamp is at the same potential and the group carries precisely the same current that operates its more majestic brother, the formidable arc lamp. Another form of incandescent lighting equally hazardous with the multiple-series system is the plain series incandescent system. The system is identical with arc systems as to the arrangement of the circuit, the only difference being that incandescent lamps are inserted into the circuit direct in lieu of arc lamps. In the Heisler series incandescent system an alternating current of five amperes is driven serially through each incandescent lamp. As each of these lamps absorbs approximately fifteen volts, if 300 lamps are in the circuit, as sometimes may occur, the line will have a potential of about 4,500 volts. When it is remembered that an alternating current of 1,800 volts was used in the electrocution of the four murderers at Sing Sing, I think no one will dispute the assertion that an alternating circuit of 4,500 volts potential is a good thing to let alone in more ways than one, for wherever the hazard to life is great, the hazard to property is equally so. In my opinion, multiple-series systems and series incandescent systems should be generally excluded from all insured buildings. There is now no legitimate reason why multiple-series lights should be found in any city, and I note with satisfaction that they are rapidly going out of use. As to series incandescent, their proper sphere is for street lighting. Doubtless some one is asking how these systems can be distinguished from the ordinary and safe incandescent systems. If a single wire comes into a building and goes to one lamp, then to another, then to another, taking in each lamp in the premises serially, one by one, you may know that the system is a simple series system, like an arc-lighting system. Being a series system, and inasmuch as incandescents are burned from it, you may be sure that it is a series incandescent system. The ordinary incandescent system has many wires of different sizes, but consists essentially of two wires, across which are placed the lamps as rungs are placed in a ladder. This is called the multiple or multiple arc system of wiring, and lamps so arranged may be turned on or off singly, or in any manner desired, and they may be of any number. In the multiple series, however, they are always run in groups, and the total number of lights in a certain place is always some multiple of a given number. Most multiple series lights are burned from the Brush system, and the number of lights in a group is generally eight. It is impossible to extinguish any light without dimming the remainder. A further identification for the Brush multiple-series system is a little black iron box with three incandescent lamps on top of it. This box is generally put up against the wall in some out of the way place. In addition to the regular group characteristic the Thomson Houston multiple-series system may be known by its abnormally large and well ventilated socket.

In many cities electric motors are placed in constant current circuits in series and operated in just the same manner as arc lights. It follows then that when this is done the entire electrical energy of the circuit goes through each motor regardless of its size. In other words, if a constant current circuit is operated by a dynamo that puts electricity to the equivalent of fifty horse power into the circuit, the entire fifty horse power goes through the little sewing machine motor and the big pumping motor with equal facility. The difference is that the resistance of the sewing machine motor is such that, in addition to carrying the ten amperes for instance of the circuit it absorbs sufficient voltage to give it the electrical energy requisite to produce the necessary mechanical power required to drive the sewing machine The pumping motor also takes the ten amperes, but the voltage it absorbs is far more than that of the little motor referred to, because of the greater amount of electrical energy it must utilize in order to return its full power. As in arc lighting, the dynamo supplying current for series motor circuits is so constructed that it automatically increases its pressure to generate the voltage which is absorbed or which ceases to be absorbed the instant any motor is started or stopped. The voltage of such power circuits is therefore constantly changing One moment it may be 2,000 volts, the next minute sufficient motors may have been started up to raise the potential to 3,000 volts. It is evident then that arc lighting circuits and constant current motor circuits are

1. Abstract of paper read before the Pacific Underwriters' association at San Francisco.

practically the same and their hazards are, therefore, about identical. I have found some credence given to the belief that constant current motors and dynamos of the same horse power have the same physical hazards. The error of this [illegible] when it is remembered that though the brushes of the motor may show a pressure of say 75 volts, still the ten amperes that are flowing through its coils are being driven by a potential of possibly 3,000 volts. As a dynamo, the arc the machine would maintain would be insignificant indeed compared with the wicked two or three inch stream of electrical fire that would be maintained across the broken terminals of the motor circuit. As with arc lamps it is well to keep at a respectful distance from these motors which, by the way, are the only kind now in use in San Francisco. Wires leading to them must always be put up with care, and in no instance should they come in contact with wood work or anything except their proper insulators, nor should they be run in any place liable to handling or where they may be possibly interfered with by merchandise, individuals or otherwise. Each such motor circuit entering a building should, moreover, be provided with an absolute break switch, through the use of which the current in the building may be instantly diverted from the motor and out of the building.

Before bringing this paper to a close I find myself tempted to mention a few of the many pernicious practices which are forbidden in insurance requirements, and which, if indulged in, will certainly occasion no little annoyance or pecuniary loss to the owner of the plant, if they do not cause fire Among these condemned practices is the use of soft rubber tubing, which cracks and becomes incapable of repelling moisture. It was once a frequent practice to secure wires in place by the use of metallic staples, but it was found that they cut the insulation and became "live" —that is, they form an exposed part of the circuit by coming into contact with the conductor. Porcelain knobs are unsuitable for outside work, for the reason principally that they afford a competent insulation only in dry weather, when it is least needed. Hard rubber hooks, which were once well thought of by many for inside arc work, have dropped into disuse because of several unfortunate characteristics. It is seldom safe to permit the suspension of arc lamps by leads—that is, by the wires which supply them with current, the objections being that the swaying of the lamp is liable to wear through the insulation at the points where the leads are secured, while the weight of the lamp may pull a lead from its proper contact piece, thereby occasioning its heating or else a very dangerous arc. Arc lamps, if used indoors, are never safe unless furnished with glass globes, and if placed in show windows or elsewhere in close proximity to easily ignited fabrics or other similar materials, the lamps should have the further protection of a spark arrester. The use of such an appliance is seldom required. The precaution of a globe is necessary, however, to prevent the falling of heated flakes or particles of carbon or copper that continually drop from a burning lamp. One never knows when or where dampness may occur in a building, and when so much depends on the keeping of moisture from conductors, it is essential that all inside high potential wires be covered with an insulation that is absolutely waterproof, and an additional safeguard is assured if each high potential circuit entering a building is provided with an absolute break switch, which, when thrown "off," will leave the interior wire as harmless as a clothesline. To say more in this direction would be to repeat what is fully set forth in the requirements of the fire underwriters governing the installation of high potential circuits.

It must not be judged from what has been stated that I am an alarmist or that I believe the electric hazard to be great compared with the hazards of other more familiar agencies. To the contrary, I wish it to be understood that the danger or the absolute safety of an electric lighting or power plant depends entirely upon the manner of its installation, and to bring about a thorough understanding of the hazards of constant current systems in order that they may be provided against, is the aim of this paper. If I have succeeded in doing so, if only in part, I am satisfied.

Flying by Means of Electricity.

Despite the repeated failures of attempts made to solve the problem of aerial navigation, there are many who believe that the accomplishment of the feat is only a question [illegible] advance in the progress of the world is not so great as some that have been made. It now appears to be generally conceded by all who have carefully investigated the matter that if there ever is a [illegible] practically. This [illegible] knowledge of Hartion to the literature of this fascinating subject An [illegible]

[illegible]

tage of the steamship—free to go through a wide stretch of air unhampered by conditions of stability of roadway or limitations of curves and gradients. It is true that it would have currents of air and head winds to contend against. These obstacles the steamship on water also encounters.

To the believer in the possibility of flying, however, this method we have outlined seems humiliating. It is not flying in the pure sense. It is telpherage. The aeronaut wishes to cut loose from the earth entirely, and to compete with the birds in an element which has been theirs for countless ages.

The method, however, which is thought to be the coming one, is that based upon the employment of storage batteries. In brief, it is this: A light storage battery capable of containing at least one horse power is to turn an electric motor in a suitable air ship, and by the means of a light source of power and a light motor the problem is to be solved.

It is generally conceded, however, that if we are to fly by electricity we must first be shot off from some suitable height in order to attain the requisite initial velocity.

Now let us examine the condition of a light storage battery. Great hopes were excited when the Faure storage cell was invented. Here was something which the world had been long waiting for and many prophesied that it would revolutionize methods of locomotion. Unfortunately these hopes have not been realized.

The lead battery answers admirably for laboratory use, where the plates can be readily repeated after they disintegrate. The faults of the Faure lead storage cell are its weight and its rapid disintegration when a severe demand is made upon it. Much invention has been wasted upon this cell. It has been modified in numberless ways to overcome the defects of weight, of the buckling of the lead plates of the cell, that is the yielding and deformation of their shape. Fairly powerful batteries are now made and are supplied to the public. In certain cases the companies take entire charge of the batteries, assuming the loss from the inevitable deterioration, charging ten per cent. a year on the cost of the battery. In a certain limited sense, therefore, the lead storage battery can be said to be a success.

The weight of the average commercial lead storage battery is about 100 pounds per horse power per hour. If one wishes to run a motor for six hours the battery should be charged for ten or twelve hours, and under the most favorable conditions, 80 per cent. of the current which is used to charge the battery can be recovered by its performance.

I have said that numberless attempts have been made to decrease the weight of the lead plates of the Faure accumulator, or storage cell. My experiments lead me to believe that moderately thick lead plates are more economical than thin light ones. The expansion and contraction of the oxides of lead which are pasted into holes and irregularities in the lead plates lead to deformation of the plate. The paste thereupon drops out of the recesses or holes which contain it and the battery loses its charge. I have replaced the lead plates by porous carbon ones containing holes for reception of the lead paste and a thin backing of lead for electrodes.

This last form of storage cell was very light and would receive a strong charge; but the plates rapidly deteriorated. Apparently we must be content in the lead storage battery with comparatively heavy lead plates. Since the weight of this form of cell is so great, and since there is apparently little prospect of the weight being reduced, it seems to be out of consideration in the question of flying.

A new storage cell has recently attracted much attention and it bids fair to compete successfully with the lead battery, certainly in the problem of flying. This cell is a modification of the alkaline storage battery or accumulator invented two or three years since in France by Desmazures. This cell weighs in rough terms only about half as much as a lead cell of the same capacity. One pole of the alkaline storage battery is of iron, while the other is finely divided copper. The liquid is potassium zincate. The zinc is deposited upon the iron, while the copper, being finely divided, can be readily oxidized.

Two American inventors, Waddell and Entz, have modified the original Desmazures cell in certain slight but important particulars. The result of the endeavors has been the production of a remarkably efficient accumulator. The saving in weight of this battery over the lead storage battery is about 1,500 pounds per car. A car furnished with this battery together with its motor weighs somewhat less than the electrical car of the ordinary trolley system.

There seems to be more hope for aeronauts in this new battery than in the lead batteries, but this hope is a small one, for although the weight of the storage battery has now been reduced to nearly one half, it is still very great; and the weight of the motor has still to be considered.

It is not probable that the future bicyclist of the air can support himself and progress with less than one horse power at his command. If he employs electricity he will find it difficult to construct an electrical motor which will yield a horse power and which will weigh under 100 lbs. With 100 lbs. in his battery and 100 lbs. in his motor, to say nothing of the weight of the gears, wings, and rudders of the flying machine, the electrical aeronaut will be heavily handicapped even for a short trip. If an initial velocity could be gained by some species of send off, like a toboggan slide, it is improble that a flying machine with such a heavy electrical equipment could be made to soar, and the unlucky experimenter would speedily find [illegible] among the debris of the machine.

Even if a lighter storage battery should be invented, of which there is increasing probability, the weight of an electric motor still will remain necessarily great. What invention may accomplish in the way of lightening electric [illegible] power. At present electric motors are too heavy to be seriously considered for the propelling agents of flying machines which are not in part balloons.

We therefore return to the first method we have described, that of a balloon ship driven by an electrical motor, which is driven by a current fed to the motor by a trolley wire, in short a modified telpherage system. This method of flying, although ignominious to one who desires to cut himself entirely free from all connection with the earth, still seems to be a possible solution of the endeavor to use the air as steamships now use the water. The new method of step up and step down converters would enable comparatively fine wire to be used to convey the electrical current from the wires on the earth through the trolleys to the balloon ship. The latter could therefore be at a height sufficient to move freely without any fear of touching housetops or trees.

The step up transformer is merely the old Ruhmkorff coil. The primary of this is supplied with a powerful alternating current, a very high electromotive force is thus generated in the fine coil of the Ruhmkorff coil, and this electrical pressure can be transmitted along comparatively fine wires to the machine where it is desired to obtain electrical power. At the machine the high pressure current passes into a step down converter or transformer, which is simply another Ruhmkorff coil, and the quantity current with low pressure is taken off the inner coil of the Ruhmkorff.

This, in brief, is the method of the step up and step down transformers. And it is possible that we may step up into the air by such a system on the telpherage plan. The stepping down can be accomplished electrically, but the problem of stepping down safely from flying machines still puzzles the aeronaut, whether he proposes to employ electricity or some other source of power.

CORRESPONDENCE.

New York Notes.

NEW YORK, August 8.—The burning of the station of the Richmond Light, Heat & Power company of Staten Island is the most important item of news to be chronicled this week. The destruction of this plant, which furnished current for all but a few lamps on the island, leaves the residents in a position to appreciate now, if never before, and to the fullest extent, what New York proper had to suffer when Mayor Grant first began that work which has led to such an extensive development of the underground system. The conflagration from an æsthetic standpoint was a magnificent sight—your correspondent was on the island at the time—but those who have since had to resort to the miserable gas jets, or worse still, candles and oil lamps, are not as enthusiastic now about the "beautiful fire" as they were on the night of August 3d. The town of St George turned out en masse and witnessed the conflagration from the hillside. Both Erastus Wiman and his son, W. Dwight Wiman, who is general manager of the Richmond company, were on hand directing their men in an effort to save a small annex office building. This was only partially burned. The Staten Island "fire department" was there also, but the fire went on just the same. Perhaps it may be an injustice to some one to mention also that a man was seen on one of the poles just outside of the building sawing the "deadly" wires about thirty minutes after the lights went out. A lesson will be drawn from the Richmond company's fire, and doubtless the new station, which is to be built immediately on another site closer to the water's edge, will be constructed according to modern ideas. President Wiman has issued a circular in which he states that it is the hope of the company to be able to continue the regular service in about sixty days. Just after the fire the Fort Wayne Electric company came to front with an offer to furnish ten or twelve dynamos and deliver them in forty-eight hours. The offer was accepted. It is probable that these machines will be set up at different points on the island, if extra power is available, and will be employed in this manner to feed the system. A number of the New York papers quoted General Manager Wiman as stating the company's loss to be $75,000 to $100,000, but on the night of the fire Mr. Wiman estimated the damage at $50,000 with full insurance.

Staten Island is nothing if not progressive. Unless the Richmond county supervisors display to an extraordinary degree that characteristic so peculiar to rural boards, the island, before long, will have its electric railway. A petition has been presented by a Brooklyn syndicate for permission to operate an overhead system. It is stated that negotiations for the purchase of the franchise of the Belt Line street railway running from Fort Wadsworth to the New Brighton and Port Richmond road, have been completed, and the syndicates desire to begin work as soon as possible after the board's permission has been secured. It is expected that the syndicate's plans will meet with the approval of the supervisors.

The White Squadron returned to New York from Fisher's Island, the scene of the naval reserve maneuvres, on Tuesday last. The fleet is now anchored in the North river and the officers have already begun active service in the metropolis with a breakfast at the Lawyers' Club. The New York Naval Reserves reached home the Sunday before. The Reserve roll carries the names of a number of

electrical men. S. Dana Green of the Edison company and Robert T. Lozier, manager of the lamp department of the same concern, pulled in the first battery's boat in the race between the first, second and third batteries. Both Mr. Lozier and Mr. Green, it will be remembered, have been identified with the electrical interests of Chicago.

The Rapid Transit commission has adjourned until August 14th. As two members of that august body have left the city no important moves by their colleagues may be expected during their absence. It is announced that the commissioners desire to obtain a consensus of the best available engineering opinion before the board makes a decision. The opinions are to be embodied, along with specifications and detail plans, in a report to the common council.

District Attorney Nicoll, it seems, has begun with a rush his effort to indict all the New York papers which published accounts of the electrical executions at Sing Sing. The grand jury brought in indictments against the following named gentlemen Joseph Pulitzer of the *World;* John A. Cockerill, editor of the *Advertiser;* George W. Turner of the *Recorder;* William F. Laffan, publisher of the *Sun;* Bradford Merrill, managing editor of the *Press;* Albert H. Hceckley, city editor of the *Journal,* and Charles R. Miller, managing editor of the *Times.* The only morning publication exempted from indictment was the *Tribune.*

"The *Tribune* was not indicted," said Assistant District Attorney Lindsay, "for the reason that it has not shown any disposition to go into the matter. It would be impracticable to get these indictments without the concurrence of the newspapers, because any one connected with a newspaper would be excused from testifying, and for the further reason that in these cases the prosecution is compelled to prove the truth of the published accounts, which is almost impossible without the concession of the newspapers."

As a matter of course the New York journalists are up in arms on the subject of the freedom of the press, and from the amount of space which has been devoted to interviews, etc., one is led to believe that the editorial heart is secretly gladdened at the thought of what will follow in the natural course of events. It may be mentioned that the *Sun's* interviews with leading statesmen of both parties showed four Democrats and four Republicans emphatic in their remarks in favor of a repeal of that section of the law restricting the liberty of the press. Chauncey Depew, as usual, covers himself with glory—that is, as far as the newspapers are concerned—by one pertinent and comprehensive remark: "The clearest light should be shed upon the taking of human life by law," says Mr. Depew, and "Hurrah for Chauncey Depew!" says the *Sun.* Had Mr. Depew only been politic there would have been electric lights in his tunnel, and then the WESTERN ELECTRICIAN might have added "Bravo, Chauncey."

Etymologists will be interested, no doubt, to learn that the New York *Manufacturer and Builder,* in deference to the *Times,* has decided to use the word 'electrothany" instead of "electrocution." The aforesaid journal deems "electrothany"to be the proper thing—"properly significant and etymologically correct."

Alas, word juggling will do no good now. "Electrocution," it is to be feared, has come to stay, both as a word and as a horrible reality.

George Francis Train is in New York. Chicagoans will be glad to know this, for Mr. Train once passed through Chicago on his way to smaller and less progressive cities. Mr. Train feels kindly toward the Fair. He had heard of it when abroad. He would gladly save it from ruin. It would please him to give to the world the benefit of a preliminary fair by taking 1,000 persons around the world in the Majestic. Electricians will be glad to know of Mr. Train's plan: "I propose," said Mr. Train, "to have 1,000 American flags on the ship, and whenever we enter a port each of the 1,000 passengers will be waving a flag. That will advertise America. On board the vessel we will have our phonograph, our electrical appliances, and specimens of all the important American inventions. It will be a fair such as will attract and interest the people of every nation. They will eagerly pay to come and see it. They will talk in our phonographs. A lot of money will be made, and the success of the World's Fair be assured." Unless the people come right forward—Mr. Train talks plainly—he will abandon further attempts to help them out of their troubles. He will go back to silence in Madison Square. He says he once went for fourteen years without speaking to man or woman, and can do it again. It is earnestly hoped that the Chicago Electric club will take immediate action to prevent this catastrophe.

The plausible Pennington of Mt. Carmel air ship fame has also turned up in New York, bringing his model along with him. The reader will remember that this alleged air ship was described in the WESTERN ELECTRICIAN when it was on exhibition in the Exposition building, Chicago. The article appeared in the issue of Feb. 14, 1891. Dr. Warren C. Spencer is master of ceremonies in New York city, and on last Tuesday he gave an exhibition of the marvelous machine to a favored few at the Academy of Music. "Mr. Pennington will reach here in about six weeks," said Dr. Spencer. "He is going to sail the ship from St. Louis He gave me his word of honor that he would be here in that time, and I know he will."

Dr. Spencer is probably from St. Louis.

The United States Electric Light company on August 2d filed the indemnity bond for $50,000 in the United States circuit court. The company was required to file under the order of Judge Wallace granting an interlocutory decree staying the order of injunction secured by the Edison company. The sureties are Marcellus Hartley and Anson P. Stokes. The United States company has also taken an appeal from the recent decision in favor of Edison, to the new appellate court. On August 4th the United States people filed an assignment of errors.

At a meeting of the Board of Electrical Control on Monday last the Empire Subway company was ordered to build subways on a number of streets for the use of the Edison company. The work must be completed by September 15th.

If Chicago was New York, instead of being only the "Windy City," or was inclined to be retaliatory, the civilized world would perhaps by this time be thoroughly posted as to the most recent innovation in the way of "New York's midsummer plague." Only one irrepressible reporter yields to the temptation, however, and in a short paragraph lets the cat out of the bag. It seems that the electric lights fed from New York stations are just as alluring to the bug species as those in Chicago. The lamps up town are attracting vast numbers of bugs, called here "hawk moths," especially when the lights are in the neighborhood of ailanthus trees, upon which the insects are supposed to feed. The pavements on some parts of Eighth avenue are so thickly covered in the evening by the dead moths that the trampling of pedestrians over the dead bodies covers the flags with a slippery green scum. New York and Chicago are quits now. Chicago may have its sand flies, but the metropolis will have to sympathize.

The United States Railway, Equipment & Construction company of New York has purchased the system of the Lockport, N. Y., Street Railway company. The work of equipping the line for electric motive power has already been commenced. The capital stock of the new organization will be $100,000.

It is understood from a representative of the Phonograph company that a new type of phonogram is soon to be introduced. The improved cylinder will be much smaller than the bulky ones now in use. It is to be no larger than a man's little finger. The recording stylus is made to do much finer work. These small cylinders will undoubtedly lead to a much more extensive introduction of the phonograph, especially as an aid in general office work and correspondence. F. L. P.

Minneapolis, Minn.

MINNEAPOLIS, Aug. 8.—The Minnesota Brush Electric company has just let the contract for putting its entire system of wires underground in the underground district. This is the first complete contract of the kind for power, arc and incandescent lighting ever let in the United States. The company securing the contract is the Standard Underground Cable company of Pittsburg. The grand total of the cost of the plant with extensions completed will be about $120,000, and the cost of the work to be completed this year will approximate $92,000. Some idea of the magnitude of the work may be gathered from the fact that 82¼ miles of cable, with all the accessories, are necessary to put in the plant. The contract requires that the system in the underground limits shall be completed and in working order by Dec. 1st of this year, the company securing the contract having put up a $50,000 bond to that effect. F. E. Degenhardt, the representative of the Standard Cable company, is highly elated over his success, having practically defeated every electrical construction company in the country in an open field. In June of last year the Brush company let a contract for 60 miles of underground cable to the Cobb Vulcanite Rubber company, which, after completing 20 miles, became bankrupt. The Brush company, after investigating the field, advertised for bids for putting in the entire plant, which resulted in the Pittsburg company's triumph.

The street car company has started another of its lines. The Western avenue and Second street N. E. extension just completed has been formally connected, and ten large motor cars have commenced their duties. There now remains

world.

arc, alternating or incandescent circuit. The brushes rotate instead of the armature. Mr. Scott thinks that the

pole he would have a flexible cord, thus doing away with the elaborate iron support on the top of the car. The trolley would be behind the car in sight of the conductor. Several experts have examined the cord and it is soon to be tested on the Lake Harriett line.

The street car company is defendant in two damage suits. The first one is brought by William Solomon for $5,000 damages. His complaint is that while riding on an electric car in North Minneapolis a couple of young men called him names and one of them struck him in the face, thereby impairing his eyesight. The conductor and driver were both witnesses to the incident and failed to come to his relief The other suit is brought by Charles Reller, to recover for the loss of a horse. Several months ago, one of his horses was killed by contact with a trolley wire on Cedar avenue and another one seriously injured.

The chief of police has issued an order regulating the members of the force in their street car riding. After this no policeman will be allowed to ride free unless he has his star displayed on his left breast. This will apply whether the officer is in full uniform or in citizen's dress. The order is made at the request of the street railway company, whose conductors have rung up passengers and have found when they came to collect the fares that they were policemen, the stars being hid under the lapels of the coats.

In St. Paul the improvements of the Consolidated company are going on with much the same vigor that is noticeable in Minneapolis. Material is now being hauled for the extension of the electric line from Tuscarora street to Fort Snelling, the bridge across the Mississippi having been completed for the purpose. The West Seventh street electric line is likely to become the next inter-urban line. When this line is completed to the Snelling bridge it will be only a short distance from the Minneapolis line running to Minnehaha. Another bridge will probably be erected at the fort, as the present one is too narrow and of too weak construction to warrant the traffic of the popular inter urban line. It is officially stated that Mr. Lowry will co-operate with property owners in building the bridge necessary. The route would be peculiarly favorable for an inter-urban line, as for much of its distance there is a high bluff on one side and lowlands on the other, effectually doing away with cross streets. The motors can make very fast time on such a line, and probably reduce the running time between the two cities to something near half an hour.

General Manager Goodrich, of the Twin City company announces that he will within a few days issue orders for all electric trains on the First avenue and Bloomington lines to swing around the Union depot loop instead of switching at Washington avenue and First avenue south.

This is an important order, and will be hailed by the traveling public with much delight. All the principal lines of the city will upon issuance of this order carry passengers to and from the Union depot without change of cars. The Western avenue division will in a few days be consolidated with the Second street, N. E. line, and these cars will pass the Union depot, crossing the steel arch bridge into East Minneapolis. For some time there has been a continuous blockade of cars in front of Temple Court on Hennepin avenue, where several lines have been required to use a turn table. The new arrangement will obviate all this. The company has surprised the gay public which frequent the lake resorts by illuminating its line between Lake Mendota and

lamps, which gave a

to the dark woods in that neighborhood. The company has also

musical

immense

awaits the

operation.

between the lake and the city. When this line is open the street

in the city limits of Minneapolis, over half of which are

pleted will be over 500 coaches and motors. All motors will carry trailers, thus making the system as convenient as it is complete.

The vexed question of transfers is again disturbing the street railway company. Under the present plan of issuing transfers good on all lines for half an hour after the time of issuance the company has been subjected to glaring frauds and abuses and has unquestionably lost thousands of dollars through the petty meanness of many of their customers. It is announced that some restrictions will be placed upon the system immediately, but just what it is has not yet appeared There is no question but that the general public would be very willing to see some limitation on the present system of transfers, as the injustice of it is apparent. F.

Toledo, Ohio.

TOLEDO, Aug. 8.—The business of the Toledo Electric Street Railway company has increased to such an extent that it has become necessary to have an assistant general manager, and the services of G J. Coleman of Cleveland have been secured for that position. F. B. Perkins, formerly of Pittsburg, Pa., is superintendent. He is popular with the employes.

This company now has in operation twenty miles of track, on most of which a 78 pound girder rail is used. It operates twenty-eight single motor cars out of a possible thirty-one, three cars only being held in reserve in case of repairs and overflow business. These cars make from 135 to 140 miles per day each.

The company employs at present five 80 horse power generators, which are run by one double compound engine, which can be increased to 1,000 horse power. An order has been placed for another generator and another engine of 1,000 horse power, which will increase the capacity to 2,000 horse power. The company's intention is to furnish power for private institutions, which is being done at present to a certain extent.

The Toledo Electric Street Railway company has begun an action to recover $250,000 from the Consolidated Street Railway company for alleged malicious interference with the construction of the plaintiff's lines. The Robisons charge the old company with maliciously and wickedly contriving and conspiring to perpetuate the monopoly of the street railway carrying business in the Consolidated company, and prevent and destroy the inauguration of any competing street railway enterprise in the city. Further, the defendants are charged with striving to impair the credit of the new enterprise, delay, and, if possible, prevent the completion of the road, using for this purpose improper means to induce property owners to withdraw their signatures to the petitions for the road, and also attempting to prevent them from selling the bonds issued, to prevent manufacturers and dealers in iron and electrical supplies from selling them to the plaintiff, and to destroy all possibility of any profit being made out of the operation of the road. From present appearances the litigation has just begun.

Omaha, Neb.

OMAHA, Neb , Aug. 8.—A contract has recently been let by the state authorities to the Lincoln, Neb., Electric Supply company for lighting the state buildings at Peru, Neb. Two hundred incandescent lamps and the necessary machinery and wiring are to be furnished. The same firm also secured the contract for the electrical work to be done at Hastings, Neb., in the new buildings for the Asylum for the Insane.

The Omaha Street Railway company is changing what was left of the old horse car lines to electric lines, and ex-

The work of erecting the lighting plant in Lincoln park, is already giving H P. K.

Pittsburg, Pa.

The Second Avenue Passenger Railway company has broken ground for the foundation of an addition, which the company is building to the power house on Second avenue.

W. E. Stevenson, of the laboratory force of the Westinghouse Electric & Manufacturing company, has gone to Atlantic City for two weeks. B. L. W.

Denver, Col.

DENVER, Colo., Aug. 8.—The electric light question has been settled by the acceptance, with some modifications, of the Consolidated Electric Light company's proposition. Incandescent lights on the all night schedule will be supplied at $2.16 2-3 per month; arc lights in the central part of the city for $12.50 per month, and outside the present incandescent districts at $10.

The combination of water power and the electric motor promises to be a most important factor in the future development of Colorado mines.

Experiments at Gold Hill stamp mill, in the Telluride district, show the feasibility and economy of the scheme. Electricity is conveyed to that mill two and one-half miles from an alternating current dynamo capable of developing 140 horse power, which is operated by water power. L. L. Nunn, general manager of the Gold Hill company, is the originator of the idea of utilizing the hitherto wasted power of the mountain streams.

O. D. Irwin, electrical engineer for the Westinghouse company, put in the motor and wires to the Gold Hill mill. The success of the scheme has stimulated other mine owners and other plants will soon be in operation in the Telluride district.

A street car line will be built by Denver capitalists in Laramie, Wyo. The Laramie Tramway company has secured a franchise giving it the privilege of furnishing railway transportation for the city either by cable, electric or horse car lines. The officers of the company are: F. M. McHale, of Denver, president; G. W. Griffith, Jr., of Denver, secretary and treasurer; directors, R. A French, F. M. McHale and G. W. Griffith of Denver and James Vine and W. B Travin of Laramie. The company has a capital stock of $100,000. E. C. D.

PERSONAL.

Geo. W. La Rue, secretary and general sales agent of the Crocker-Wheeler Motor company, New York city, was in Chicago last week.

John I. Beggs, manager of the central district office of the Edison General Electric company, is in New York attending the Edison convention.

John D. Challar of Washington was in Chicago last week. Mr. Challar will visit the Pacific coast, where he is interested in electric railway enterprises.

Eugene Cowles, president of the Cowles Aluminum company of Lockport, N. Y., is spending a few weeks at the Thousand Islands and in the Adirondack mountains.

W. S. Andrews of the Edison General Electric company, New York, was in Chicago last week. Mr. Andrews had been visiting the stations in Rochester, Detroit, Minneapolis and St. Paul, and reported the Edison interests in good condition.

NEW INCORPORATIONS.

Penn Yan Electric Light & Power company, Penn Yan, N. Y.; capital stock, $100,000; manufacturing electricity for light, heat and power.

Brighton Water and Electric Light company, Brighton, Colo.; capital stock, $20,000; to supply the town of Brighton with water and electric light.

Highland Electric Light & Power company, Highland, Ill; capital stock $8,000; to furnish electric light and power; F. Wild, Highland, Ill.

Edison Electric Illuminating company, Atlanta, Ga.; capital stock, $10,000; generating electricity and furnishing it for all the purposes to which it may be applied.

Continental Development company, Richmond, Va.; capital stock, $800,000; machinery and electric equipments, general manufacture, real estate and improvements.

Maryville Electric Light & Power company, Maryville, Mo ; capital stock, $25,000; to supply the city of Maryville with electric light and electric power; Wm. A. Ross, Maryville, Mo.

Wagner Electric Manufacturing company, St. Louis, Mo.; capital stock, $25,000; to manufacture, hire and sell electric apparatus, machinery, supplies, etc.; Henry Digby, 322 Pine street, St. Louis, Mo.

Steubenville Railway and Electric company (incorporated in West Virginia), Steubenville, O.; capital stock, $100,000; operating electric street railway in Steubenville, O.; also supplying light and heat; Donald B. Toucey, 261 Broadway, New York, N. Y.

Crescent Insulated Wire & Cable company, Trenton, N. J.; capital stock, $50,000; to manufacture an insulated compound for the covering of wires and cables, and the manufacture of electrical appliances; Murray, Murray Trenton, N. J.

Cotton Compress Co. and Manufacturing company, Brenham, Washington Co., Tex., capital stock, $150,000; ginning, baling and compressing cotton, manufacturing cotton seed oil, operate electric plants, manufacture and sell etc. [illegible], jr., Brenham, Tex.

ELECTRIC LIGHT.

At Louisville, Ky., the Light, Heat & Power company has just been organized for the purpose of operating an electric light plant.

The city council of Brownwood, Tex., has granted the Brownwood Improvement company permission to erect an electric light plant.

The installation of an electric light plant is being discussed in Milton, Fla. J. B. Crossland of Pensacola is investigating the subject.

It is stated that the city of Newnan, Ga., has signed a contract with W L Dresser of Albany, N. Y., for the erection of an electric light plant.

N. E. Whitaker, Thomas O. Brien, R. Stainaker and others will organize a stock company at Wheeling, W.Va., for the erection of an electric light plant.

The California state authorities will put an isolated electric lighting plant in the capitol at Sacramento. The building will be wired for about 800 lamps.

The Fort Wayne Electric company, through W. J. Morrison and A. J. Corriveau, is about to present an arc lighting plant to McGill university, Montreal.

The Electric company of Virginia has recently erected an additional building 38x68 feet at Norfolk, put in new machinery, and increased the capacity of its electric light plant.

The Brighton Park Mutual Home & Investment company of Baltimore, Md., has been incorporated to erect electric light plants, gas works, deal in real estate, etc. The capital stock is $250,000.

Contract has been let for the erection of an electric light station for the Carolina Light & Power company at Cotton Shoals, on Little Horse creek, near Graniteville, S. C. Water power will be utilized.

A bill was recently introduced in the legislature of Georgia to appropriate $10,000 for the establishment of an electric light plant and a heating plant at the State Deaf and Dumb asylum at Atlanta.

Two new electric light plants have recently been incorporated in Atlanta, Ga.—the Georgia Electric Light company, with a capital of $600,000, and the Edison Electric Illuminating company, capitalized at $10,000.

According to report, not only will all the streets and public buildings, but the majority of the private dwellings, be lighted by electricity at Shenandoah, Va. The town is a comparatively new one, and has a population of about 2,500.

The St. Catherines and Welland Canal Gas Light company, of St. Catherines, Ont., has applied to the city council for the privilege of erecting poles and stringing wires on the streets of the city for the purpose of supplying illuminating and heating power.

The Iron Cross Investment company has been incorporated at Basic City, Va., with W. V. Kirk of Paw Paw, W. Va , president; E. P. Cahill of Hancock, Md., vice-president, and J. N. Kirk, secretary, to erect electric light plants, gas works, deal in and improve real estate, etc. The minimum capital stock is $20,000, and the maximum capital $50,000.

The town of Marblehead, Mass., has decided to establish an electric lighting plant of its own. A committee was appointed, and it has located the lights, drawn up the contracts, fixed upon a site for the station, and ascertained the cost of the plant. The selectmen will soon be asked to call a town meeting for the purpose of acting on the recommendations of the committee, after which, if they are accepted, it will not be long before the plant will be in operation.

Work has been commenced in connection with the municipal central station at Dublin, Ireland. The site is about one-quarter of an acre in extent. The private lighting plant will comprise three 300-horse power engines, each of which will drive a 2,000 volt alternator. The public lighting plant will comprise three 60-horse power engines, and three 55 light dynamos. The cables will be laid in iron piping. The public lights will probably be started in November.

Reports have been in circulation for some time to the effect that the Thomson-Houston Electric company of Boston and the Fort Wayne, Ind., Electric company had purchased a controlling interest in the Municipal Electric Light company of St. Louis, Mo. James Campbell, the broker, who has been in New York for some time in connection with Municipal Electric Lighting company matters, is reported as saying that the Thomson-Houston company and the Fort Wayne company are seeking to gain a very substantial interest in the St. Louis company, but not the control.

A prominent dentist says: "We now have the electric light to aid us in our dental operations, and I find by its use I can discover imperfections in cavities I have prepared that had previously escaped my attention. Why? Because the electric light gives a paler white light, and it is more intense than daylight. This is particularly so in that form of decay known as the white decay. You may prepare the cavity with the ordinary care, having it seemingly perfectly dry, and a magnifying glass will show you no imperfections, but with the aid of the electric light you can find them."

At the government dockyard at Port Adelaide, Australia, there is in course of construction a traveling electric light plant for use on the railways. It consists of an ordinary locomotive engine, a truck upon which is fitted a portable engine and the dynamo, and the weed stripper, which is used for clearing the railway lines of undergrowth. The

plant, when completed, will be used to enable the navies to carry on their work as much as possible at night, when their operations will be less hampered by the train traffic than during the day. Telegraph poles, upon which the wires are carried and the lamps hung, will be erected at each halting place where their services are required.

Locomotive No. 34, which has been rebuilt in the Chicago and Alton shops at Bloomington, Ill., is unlike any other in existence, except one at Bay City, Mich. This locomotive will, it is said, consume its smoke and condense the exhaust steam, similar to a marine engine. It is provided with electric dynamos, and the headlight and the numbers of the engine and train will be illuminated with electricity. The entire train drawn by this engine and the signal lamps will likewise be illuminated by electricity. The headlight sits low on the front of the engine, the dynamo standing where the old headlight was, and the view from the cab is entirely free from obstruction. It is reported that if this locomotive, thus equipped, proves a success, similar improvements will be introduced upon all the passenger engines of the Chicago & Alton road.

ELECTRIC RAILWAYS.

Lockport, N. Y., is going to have an electric street railway.

It is stated that electricity will be the motive power of the new street railway of North Danville, Va.

The Chattanooga, Tenn., Union Railroad company is said to be investigating a storage battery system.

The Hagerstown, Md., Electric Railway company has been granted a franchise to build an electric railroad.

The Capital City Land company of Raleigh, N. C., lately organized, will probably build an electric railroad.

H. V. B. Smith is said to be making efforts to secure the building of an electric railroad from Crossville to Harriman, Tenn.

The Dandridge, New Market & Indian Cave Railway company of Dandridge, Tenn., will, it is reported, build an electric railroad.

The Macon City & Suburban Street Railway company of Macon, Ga., is reported as about to erect an electric power plant at a cost of $35,000.

Paul W. Smith and others have applied to the city council of Montgomery, Ala., for a franchise to build a street railway to be operated by electric or other power.

The Dallas, Tex., Consolidated Traction Railway company reports that it has changed a portion of its line from horse to electric power, and will continue in the same direction as fast as practicable.

The employes of the Newark, N J, Passenger Railroad company employed on the electric line which that company recently acquired struck against a reduction of wages last week. The company was not greatly embarrassed.

A syndicate has applied to the city authorities of Christiana, Norway, for permission to construct an electric line through the streets. Experts have been dispatched to Berlin, Halle and Frankfort to investigate the workings of electric tramways in those cities.

The Villard interests in Milwaukee, according to a press dispatch from that city, are in a fair way to control the entire street railway interest of the Cream City. Negotiations are pending for the purchase of the roads not now in the control of the Villard syndicate.

The Detroit *News* reports that at a recent trial in that city of a new storage battery invented by Charles Logan of London, England, a 70-ton car was easily propelled eight miles at the rate of 14 miles an hour. It is claimed that the battery is good for a day's work at a speed of 13 miles an hour.

The Boston *Journal* is authority for the statement that Edison is at work on an electric motor for Henry Villard. The machine is to be introduced into railway work, and will, according to the same authority, "develop at least 1,000 horse power." When it is completed it will no doubt be an object of interest.

The highway committee of the Paris Municipal Council has decided in favor of the construction of a subterranean electric tramway from the Bois de Boulogne to the Bois de Vincennes, passing under the Boulevard Diderot, the Rue de Rivoli, the Place de la Concorde, and the Avenue des Champs Elysees. The project as outlined by M. Bertier provides for an underground tubular road eleven kilometers in length, and similar to the South London line. It would be lighted by incandescent lamps.

The Cicero & Proviso Electric Street railway company has had reason to complain of its night patrons. P. H. Quade, its superintendent, was before Justice Hall at Austin recently, charged with assault on Charles H. Hitchcock, Jr. When he was dismissed he began suit for $10,000 damages against Hitchcock on the ground of false imprisonment. Mr. Quade's attorney, Judge Prendergast, said that his client's arrest was due to an attempt to maintain order on one of the trains of the road. Hitchcock and three other men were involved, and all of them will be arrested, the counsel said, on a charge of assault.

The Washington correspondent of the *Chicago Daily News* announces that an important contribution to the literature of street railway locomotion is about to be submitted to President Harrison by the commission which he named to examine into the question of rapid transit for Washington and the district. The commission visited the principal cities in the United States and secured reports from leading capitals of Europe. The report is exhaustive of its subject and will fill 500 printed pages with elaborate illustrations. The commission favors a subway system for electric railways, lighting, telephone and telegraph companies. The storage battery system is regarded as the ideal one, although the committee thinks it is not above the experimental stage.

The electric railway at Sissach, Switzerland, has recently been opened for general traffic. It is about two miles in length, narrow gauge, and almost level, the worst gradient being only 1.2 per cent. The line runs through a fine broad highway. A sufficient waterfall furnishes power to a low-pressure turbine, which drives a 35 kilowatt dynamo, giving 50 amperes at 700 volts. The current is led to overhead conductors and returned by the rails. Fluid insulators fixed on wooden posts carry the conductors five metres above the ground. The rolling stock consists of one motor car weighing 6,000 kilograms, four passenger cars and four freight cars. The motor car is driven by two series-wound motors, each of which drives one axle at a mean speed of 17 kilometres per hour. The entire cost of line and equipment was $75,000. The Oerlikon Works supplied the whole of the plant.

ELECTRIC MINING.

The Main Jellico Mountain Coal company, of Kensee, Ky., intends to put in an electric light plant at its coal mines.

The Virginius company of Colorado has contracted with the Edison General Electric company for the erection of a plant for the transmission of 95 horse power, three and a half miles over the range, 14,000 feet high. Electricity will also supersede steam in the working of both the Virginius and Monarch mines this summer.

TELEPHONE.

The Bell Telephone company of Canada has absorbed the Federal Telephone company, and again enjoys a monopoly of the telephone business in that country.

The chamber of commerce of Breda, Holland, has asked the government to introduce a bill providing for the purchase by the state of all telephone lines. If the government should not be prepared at once to carry out these proposals, the chamber suggests that the state should at least exercise such a control over the telephones that contracts detrimental to the public interest may be prevented.

At Grand Rapids, Mich., two youths of sixteen and eighteen years respectively, sons of Rev. Charles Fluhrer and E. A. Mosely, became interested in electricity through studying it at home. By using a Bell telephone as a model they constructed three instruments and put up a wire. Their line was recently discovered by a lineman of the telephone company, which has commenced suit against the fathers of the boys for infringement of the patent.

A portable telephonic apparatus for use in coal and other mines has been devised by M. Berthon. It is contained in an oak box with handles. The box contains a magnet in connection, a "call" arrangement, an alarm bell, an induction coil, switch for the microphone battery, three cells in ebony cases, terminals for making connection with a wire conductor, and the Berthon-Ader apparatus. The whole is placed in a leather case provided with straps for convenience in carrying. With a well-insulated conductor carried down the shaft, and with the employment of "flying" or portable wire, communication with those on the surface is possible from any part of a mine.

TELEGRAPH.

Fire recently destroyed the two-story frame building at Colorado avenue and Forty-sixth street, Chicago, occupied by the belt line of the Wisconsin Central railroad as a transfer telegraph station. The loss is estimated at $2,500.

Messrs Hosmer and Skinner, representing the Canadian Pacific railway, have been elected directors of the Halifax & Bermuda Cable company to represent the controlling interest recently secured by the former company. It is intended to extend the line to Jamaica and the British West India Islands.

MISCELLANEOUS.

There are now running in Brockton, Mass., about 130 electric motors for shoemaking and other purposes.

The Thomson-Houston Electric company has declared its usual quarterly dividend of $1 per share for common stock.

Over $4,000 has been pledged for the Plymouth, N. H., proposed electric light plant. The intention now is to raise the amount to $10,000.

A rapidly revolving brush, which gets its motive power from a small electric motor, has been found to operate practically in the grooming of horses.

The Edison General Electric company is adding four new buildings to its plant in Schenectady, N. Y. When completed, the plant will consist of twenty-one brick and thirty-five frame buildings.

It is said that a new cane has been brought out with a tiny incandescent lamp at the top, supplied by a miniature storage battery. It would be useful for reporters looking for street numbers at night.

Searle Hill, a prominent farmer and horseman of Warren, Wis., was out driving with his two sons one day last week, when he was struck by lightning and instantly killed. The boys were fatally injured. Both horses were killed by the shock.

Thomas Edison has received many honors and titles in his lifetime, says the *Chautauqua Assembly Herald*, but it

[illegible] enter the technological institutions which devote especial attention to electrical engineering.

[illegible] obtaining ideas for local use, has submitted a report favoring a subway for electrical railways, for lighting apparatus and for telegraph and telephone companies.

The [illegible] ports 281 new, completed corporations in the United States for the week ending July 31st, with a total capitalization of $88,023,750, including 16 light, heat, power and trans[illegible]

L'Eletricita states that a project for the construction of an electric railway from Aosta to the borders of France and Switzerland at Pre Saint Didier, a distance of between 20 and 30 miles, has been laid before the Italian minister of public works. This would be by far the longest electric railway in Europe. Water power would be employed.

Electricity may revolutionize leather tanning. Two tanneries, one in Paris and the other in London, are successfully employing the invention of Worms and Bale. The principal feature is the circulation of an electric current through the tanning liquor. By this method it is said that an operation is completed in four days which ordinarily requires from seven to eight months.

The *Chicago Herald* finds occasion to praise the rearrangement of the electric fountain at Lincoln Park: "The streams ascend in parallels," it says, "and when curved fall from agreeable heights or rise at pleasing angles. The color schemes now displayed indicate a true sense of beauty and the manipulation of both lines and hues shows dexterity and knowledge. The effects are weird, fantastic and beautiful. Thousands watch the prismatic play with delight."

A large and interesting power transmission plant has been in successful operation at Oyonnax, in the east of France, since March, 1890. Power is obtained from a cataract five miles from the town, where two 105 kilowatt 2,000 volt Thury machines are coupled direct to two horizontal turbines. The current is transmitted on the three-wire system to two 120 horse power 1,800 volt motors, driving direct on to two 125 volt 600 ampere dynamos, which supply current to the town on the three-wire system. The commercial efficiency of this system is said to be 76.2 per cent.

A recent statement of Dr. Stephen H. Emmens of Emmens, Pa., is to the effect that he has perfected a process for converting pig iron into wrought iron by means of electricity. The process is simply an elaboration and adaptation of existing methods of electrical deposition, and by this means Dr. Emmens claims to be able to produce from any grade of pig iron a ductile malleable iron of almost chemical purity, which only needs washing, heating and rolling to make it equal to the best quality of Swedish iron. The inventor of this novel process claims that he can produce wrought iron by this method at a lower cost than the ordinary process of puddling, and still further economy results from the use of low grades of pig iron made from ores that are too impure to be used by existing process of conversion.

During a thunderstorm at Aylesbury, England, on July 27th, nine persons attending a flower show were struck by lightning, and three of them were killed. On July 24th a violent thunderstorm passed over Carlisle, Pa. During the progress of the storm lightning struck a shoe factory. At the time there were 300 hands employed in the building, most of them being women, and when the shock came a panic-stricken crowd rushed for the doors. Several of the young ladies were slightly shocked, while three fell to the floor unconscious, thus adding to the confusion. Misses Spangler and Johnson were severely injured. Six other young lady operators were seriously injured, beside being bruised in the rush. The lightning also [illegible] cut two shoe machines [illegible] other injury to the building, though no fire resulted.

The $10,000,000 Pennington Air ship company of Burlington, Ia., has dissolved in thin air. Not a [illegible] stock could be sold to the general public, and hence the scheme collapsed. The *St. Louis Globe-Democrat* reports, however, that the construction of the large air ship has been quietly going on in the fair grounds in that city, and that the ship is now nearly complete. The machine is cigar-shaped and nearly 70 feet long by 20 in width. The sections are of aluminum and are about three feet in length by about two in width and turtle-backed. These have all been completed, and all that remains to be [illegible] them together, which will be done in two large circus tents. The machine is designed to carry several persons, and the first ascension will be attempted early in August. The machine is designed only for exhibition purposes, and is controlled by a number of St Louis gentlemen, foremost among whom is Rolla Wells. The exhibition flights will be confined entirely to the fair grounds, and at a height not exceeding 50 feet.

TRADE NEWS.

T. J. Murphy has removed from [illegible] avenue, New York, to the Electrical Exchange [illegible] Liberty street, New York.

The Star Head Light [illegible] Rochester, N. Y., has recently received an order from the Spokane Cable Rail

way company of Spokane Falls, Wash., for 32 brass electric headlights.

[illegible] who claims to have discovered what electricity is, announces that he will be at the Grand Pacific hotel Tuesday, August 18.

F. P. Little & Co., constructing and electrical engineers, 111 East Seneca street, Buffalo, N. Y., report the prospects for fall business as very flattering. They have just secured a $15,000 contract for wiring at Albany, and have a number of other important contracts on hand.

E. T. Orne, 112 Randolph street, Chicago, has secured the contract to fit up the new *Herald* building in this city with his electric speaking tubes. He has decided to introduce the Partrick & Carter company New King annunciator and will use one hundred or more of this pattern.

The Western Electric company has just issued a new and handsomely illustrated catalogue of over 300 pages. The book forms a comprehensive record, with descriptions, of the goods sold by this great company, and its size and the variety of its contents well exemplify the magnitude of the business of the house. It is supplied with a carefully arranged index and can not fail to be of great value to any one desirous of purchasing electrical supplies of any kind.

The catalogue just issued by the Milliken Brothers, New York and Chicago, is handsomely illustrated by half tone reproductions of photographs of buildings in which Phœnix columns of iron and steel are being introduced, and also street railway and electric light poles, of which this company makes a specialty. The catalogue will prove interesting to all who are interested in iron work, to builders, architects and engineers. An able article on the use of iron and steel columns is one of the best features of the catalogue.

The R. D. Nuttall company of Allegheny, Pa., has purchased the business of the Electric Railway Specialty company of 29 Broadway, New York. The capital stock of the R. D. Nuttall company will be increased to $500,000 for the purpose of extending the business. J. F. Porter, manager of the Electric Railway Specialty company, will remove to headquarters at Allegheny and take charge of the business department, leaving Mr. Nuttall more time for the supervision of the manufacturing and designing branch of the business. Messrs. Carey & Moyer of the Specialty company will travel for the company.

The Ball Engine company of Erie, Pa., has issued a new illustrated catalogue, showing its simple, tandem compound, cross compound and triple expansion engines for electric lighting and power and general manufacturing. In the introduction the company says: "The points of value to which we especially invite attention are simplicity and compactness; the solidity and strength of the bed; the unusually large bearings and wearing surfaces; excellence of material and workmanship; economy, durability, good regulation, smooth and quiet running. We spare no pains in the inspection of our work, using first class material only, and confidentiy assert that these engines are unsurpassed. Our past experience has suggested improvements, of which we have availed ourselves, to bring our engines to a high state of perfection."

The announcement is made of the formation of a new corporation under the title H. Ward Leonard & Co., whose principal office will be in New York city, and whose business will be that of electrical engineering generally, giving special attention to electric motor appliances, the transmission of power, the installation of central station lighting and power plants, the concealed wiring of large office buildings, hotels, etc., and plants in which advantages can be obtained by the combination of apparatus of various companies, such as alternating current systems, storage batteries, arc lights, etc. A feature of the business of this concern will be supplying expert information regarding engineering matters, the operation of different plants and the best methods and system of accounts in connection with the operation of electrical plants. Such information will be supplied by correspondence at a very moderate charge per annum. The company will be actively in business before [illegible] in the [illegible]

BUSINESS.

[illegible]

capacity for the new power station of the Davenport, Rock Island & Moline Electric railway. This is one of the largest heaters ever built for this purpose, but its successful operation is assured. Baragwanath & Son report a very active business in prospect, already having booked a sufficient number of orders to keep their factory employed for several months in the future.

The Chicago Electric Motor company has met with most satisfactory results in the introduction of a new electric motor and fan placed on the market at the beginning of the present season, and in order to keep the factory in operation during the entire year a repair department has been added. Machinery has been purchased and every facility possible has been provided, not only for a line of general repair work, but for the rewinding and repair of generator armatures of all makes, and for the rewinding and repair of street railway and stationary motor armatures. A number of experienced men have been employed.

ELECTRICAL PATENTS.

Issued Aug. 4, 1891.

456,940. Electro Magnetic Cut-out. Sylvanus H. Cobb, Hyde Park, Mass.

The object of the device is to protect electrical instruments against abnormal currents. The device is capable of being operated by currents of feeble strength, as, for example, what are known as "sneak currents," by means of contacts which are closed and held closed by the current, and which also receive without injury much stronger currents than are necessary to operate.

456,970. Car Propelled by Electricity. Sidney H. Short, Cleveland, Ohio.

456,979. System for Conducting Electric Currents. Edward Britt, Davenport, Iowa.

The described is a series of distinct sectional electrical conductors, which, by means of pressure, are brought into electrical connection with a continuous main electrical conductor, and when relieved from such pressure will automatically become disconnected.

456,997. Coupling for Electric Light Shades. Philip Levison, Chicago, Ill.

457,015. Trolley for Electric Railways. Sidney H. Short, Cleveland, Ohio.

457,016. Electric Car Brake. Edmund Verstraete, St. Louis, Mo.

The armature of the magnets being fixed originally by the wheel, with the magnets themselves being shown to move toward the armature, by the passing of the current through the magnets they are drawn against the armature and by frictional contact serve for the operation of "braking."

457,030. Electric Clock. Walter K. Menns and Walter J. Dudley, Everett, Mass.

This invention relates to an electric clock of that class in which a time-measuring pendulum controls in its vibrations the circuit of an electro magnet, which in turn actuates an impelling device, by which an impulse is given to the pendulum and its oscillating movement thus maintained for an indefinite period of time.

457,036. Electric Motor for Street Cars. Elihu Thomson, Swampscott, and Edwin W. Rice Jr., Lynn, Mass.

457,058. Electric Track Signal. Myron W. Parrish, Detroit, Mich.

This invention consists, essentially, in utilizing the car wheels to form parts of a closed magnetic circuit from one pole to the other of the brake magnet, so as to constitute a part of a closed magnetic circuit armature for the magnet.

457,065. Armature for Dynamos or Motors and Method of Winding the Same. Ferdinand A. Wessel, Brooklyn, N. Y.

457,067. Electric Car Brake. Craig R. Arnold, Sharon Hill, Pa.

457,072. Incandescent Lamp Socket. Waldo C. Bryant, Bridgeport, Conn.

457,090. Rheostat. John A. Mosher, Abilene, Kan.

457,102. Electric Railway Motor. Norman C. Bassett, Lynn, Mass.

457,105. Electric Conductor Support. Eben M. Boynton, West Newbury, Mass.

This invention relates to an overhead continuous electric conductor support for bicycle railways.

457,106. Electric Conductor. Eben M. Boynton, West Newbury, Mass.

This invention relates to the use of the overhead guide beam of a bicycle railroad for the purpose of an electric conductor. By constructing the beam of two separate metallic rails electrically insulated one from another, one can be utilized for the outgoing and the other for the return current. Suitable contacts, either rollers or brushes, conduct the current from one of the overhead rails to the motors, and from the same back to the other rail.

457,109. Socket for Incandescent Electric Lamps. John Criggal, Newark, N. J.

This invention consists of an incandescent electric lamp provided with a base of suitable non-conducting material, said base having a screw threaded shank and metallic eyes at the opposite points of said shank, in [illegible] wires that engage the threaded shank and the eyes of the same, so as to firmly interlock therewith and transmit the current to the filament in the lamp.

457,[illegible]. [illegible] Switch for Electric Systems. Chris. [illegible], Milwaukee, Wis.

457,116. Galvanic Battery. John R. Hard, New York, N. Y.

This invention relates to open circuit dry batteries. The novel features claimed are: A cell in which the positive element is a zinc cup of tubular form, and the negative element is a rod or piece of chloride of silver, this latter being immersed in an excitant mixed with some mucilaginous or gelatinous substance, which renders it too stiff or immobile to flow. The zinc cup constitutes one pole of the cell, and a wire of silver embedded at one end of the negative element and projecting outward through a closing plug or stopper in the cup constitutes the other pole of the cell.

457,127. Electric Hand Fan. William B. Luce, Boston, Mass.

This invention has for its object to provide a portable fan adapted to be operated by electrical means. It consists of a fan comprising a handle or holder, a movable fan or series of fan-blades mounted to rotate in bearings on the holder, an electric motor so mounted upon the holder and arranged to rotate the shaft of the fan and suitable connections between the motor and a source of electricity, whereby the motor may be driven, and a circuit closing and breaking device located within or upon the holder, so that the user of the fan may cause the rotary movement thereof to cease at pleasure by the manipulation of the button connected with the circuit closing and breaking device.

457,135. Railway Signal. William C. Serrell, Bayonne, N. J.

In this invention the batteries are placed at intervals along the line, and are connected in such a manner that the batteries in their normal position oppose each other, and the alarm mechanism upon the engine is only brought into action when the circuit is closed through two trains when they come nearer than the prescribed distance; this system is also connected with the switch mechanism in such a manner so that when the switch is set to the siding a circuit is partially closed, so that a train approaching the switch or siding completes the circuit connections, and indicates that the switch is open.

457,141. Electric Arc Lamp. Xavier Wertz, New York, N. Y.

This invention relates to improvements in the construction of electric lamps, which is based on the formation of a voltaic arc located in a glass bulb or globe in which a vacuum has been established, so that the carbon will burn for a considerable length of time, and the lamp be applicable for use in the same manner as electric glow lamps without requiring any forward feeding of the carbons.

457,151. Coupling for Electric Incandescent Lamps. Isaac J. Flagg, Clinton, Mass.

457,164. Electric Smoothing Iron. Willis Mitchell, Malden, Mass.

This invention releates to tailors' irons and laundry irons, which are heated by removable coils or spirals of wire forming part of an electric circuit.

457,226. Brush Holder for Dynamo Electric Machines. Sidney H. Short, Cleveland, O.

457,239. Printing Telegraph. Henry Van Hoevenbergh, Elizabeth, N. J.

The object of this invention is to provide an instrument capable of printing rapidly from either of two type wheels, which is easily maintained in unison with the transmitter, operates with a small amount of battery power, is not affected by considerable changes in the strength of current, and is controlled by a simple form of transmitter.

457,240. Electric Railway. Samuel E. Wheatley and John W. Schlosser, Washington, D. C.

This invention relates to that class of electric railways in which a working conductor extending lengthwise of the road is divided into short lengths or sections, each of which is fed during the time that the car is passing over it from a continuous main lead or conductor through an automatic switch.

457,296. Electric Fence Station Device. David H. Wilson, Normal, Ill.

457,300. Electric Switch. Waldo C. Bryant, Bridgeport, Conn.

457,301. Electric Switch. L. D. Castor, Philadelphia, Pa.

457,327. Commutator or Contact Brush. Leonard Paget, New York, N. Y.

457,330. Automatic Brush Shifter for Dynamo Electric Machines. Thomas E. Adams, Cleveland, O.

The invention has reference to automatic brush shifters designed for use more particularly in connection with the Brush constant current dynamos and other dynamos of this type.

Reissue 11,123. Electric Elevator. Francis B. Perkins, Boston, Mass.

This invention relates to elevators of that class known as "drum elevators," in which the elevator car or platform is raised by winding the hoisting rope or cable upon a drum set in rotation by means of an electro motor. The present invention has for its object to provide elevators of the class referred to with an electrically controlled brake mechanism in circuit with the motor, and normally operative by the starting and stopping mechanism to release the brake and permit movement of the cars as long as the circuit of the motor is completed, but which becomes inoperative as soon as the circuit of the motor is broken, so that in case of accident to the motor or its circuit the elevator car can not be moved by operating the starting mechanism.

THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.

In a letter from the INSPECTOR of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says: "A Thoroughly Reliable and Desirable Wire in Every Respect."

The rubber used in insulating our wires and cables is specially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

What is Electricity?

An Announcement.

By some discoveries I have made I am enabled to give, I believe, the final answer and demonstration to this ancient question. The discussions of this have been mainly before scientific bodies, but as any intelligent audience can be entertained and readily understand the explanations of the telegraph, electric light, lightning and all electrical phenomena, I propose to answer the question and make known my discoveries by a popular lecture delivering the first in Chicago in October.

More statements will be made when the time and place of the lecture are made known.

Trusting that sentence of boldness will be withheld until in future I make known why I was obliged to adopt this method of announcement, I am respectfully,

ELECTRIC SECRET SERVICE CO.,

45 BROADWAY, NEW YORK.

Owning the patents of Mosher, Gill, Hatch, Foote, Kintner and Moore for

INDIVIDUAL TELEGRAPH CALL AND CUT-OUT APPARATUS.

OTHER PATENTS PENDING.

The only practical and reliable system of electric selection invented.

Use either ***Morse Key*** or ***Automatic Transmitter.***

From every station selected an ***Automatic Answer back*** is received.

Gong rings until shut off by operator.

Any office on line can be selected without disturbing the others and either called up or cut out. No interference with regular telegraph service. No resistance added to main line. Easily applied. Economical. Convenient. Reliable.

Applicable to arc lights, singly or in groups; fire alarm service; police telegraph; electric motor circuits; railroad signals, etc.

The public is warned against infringing companies and devices.

For terms and other particulars, address as above.

"WARD" ARC LAMPS,

FOR CONSTANT POTENTIAL CIRCUITS.

THOUSANDS IN USE

On both Isolated and Central Station Plants.

WE GUARANTEE OUR LAMPS ELECTRICALLY AND MECHANICALLY.

In corresponding please give full particulars and state voltage.

ELECTRIC CONSTRUCTION AND SUPPLY COMPANY,

Phenix Bldg., CHICAGO, ILL. 18 Cortlandt St., NEW YORK CITY.

ESTABLISHED 1881.

ELECTRICIAN PUBLISHING COMPANY'S

HAND-BOOK SERIES.

22,000 Copies published to date. An Astonishing Record.

Dynamo-Tenders' Hand-Book.

By Lieut. F. B. Badt.

Fourth Edition, Eighth Thousand.

94 Pages, 70 Illustrations, Flexible Cloth Binding, Type Page 6x3 inches.

The only PRACTICAL Dynamo-Tenders' Instruction Book in the English language. Just the book for Dynamo-Tenders, Linemen, Stationary and Marine Engineers who wish to learn how to operate and care for electric light or power plants. Moonlight schedule for 1891.

Bell-Hangers' Hand-Book.

By Lieut. F. B. Badt.

Second Edition, Fourth Thousand.

106 Pages, 97 Illustrations, Flexible Cloth Binding. Type Page 6x3 Inches.

Designed for those engaged in selling, installing or handling electric batteries, electric bells, elevators, house or hotel annunciators, burglar or fire alarms, electric gas lighting apparatus, electric heat regulating apparatus, etc. The only book of the kind published.

Incandescent Wiring Hand-Book.

By Lieut. F. B. Badt.

Third Edition, Seventh Thousand.

72 Pages, 42 Illustrations, Flexible Cloth Binding. Type Page 6x3 Inches. Five Tables, 12x18 Inches.

These tables give *at once* and without any calculation the size of wire required in each case for any percentage of loss.

It is a book for practical wiremen and learners, and does not require any previous knowledge of wiring. It differs in this respect from other wiring tables, or computers.

The book contains full illustrations and complete information concerning methods of running wires, location of safety devices, splices, insulation, testing for faults, wire gauges, wiring of fixtures, elevators, buildings, etc. The only book of the kind published.

Electric Transmission Hand-Book.

By Lieut. F. B. Badt.

First Edition, Three Thousand Copies.

97 Pages, 22 Illustrations, and 27 Tables. Flexible Cloth Binding. Type Page 6x3 Inches.

This book contains all practical information for power producers, capitalists, agents of hydraulic and electric companies, engineers, motor inspectors and other persons interested in electric power transmission. By means of the tables anybody can find at once cost of plant for least operating expenses, or for minimum first cost of installation.

The book gives all necessary information concerning motors, and rules for ascertaining horse power of motors, driving various classes of machinery, as hoists, pumps, street or tram cars, fans, etc.

Twenty-seven new and original tables give more information on the subject in a small space than any book heretofore published on the same subject.

Each Work Sent Postpaid on Receipt of One Dollar.

WRITE FOR CIRCULAR AND CATALOGUE.

H. WARD LEONARD & CO.

We will do no MANUFACTURING and will do no SUPPLY BUSINESS, neither will we, under any circumstances, act as the selling agents of any concern, directly or indirectly.

We will, however, act for the purchaser, either as Consulting Engineers, Supervising Engineers, Inspectors or Purchasing Agents. When acting in this way we will make the following charges, based upon contract price:

For making preliminary plans, designs, distributions and estimates ..... 1 per cent.
For making final plans and specifications ..... 1 per cent.
For drawing and executing contract on behalf of the purchaser ..... 1 per cent.
For supervising an installation made by another contractor ..... 3 per cent.
For acting on behalf of the purchaser in making the settlement with another contractor ..... 1 per cent.
For acting as the agent of the purchaser, from the beginning to the final settlement of a contract, including the making of estimate plans, determinations, specifications, contract, supervising the installation, final inspection and report and final settlement ..... 5 per cent.

It will be seen from the complete schedule given above that the purchaser will be able to obtain our services for any portion of the work, and under terms which are so reasonable that there can be no question in the minds of those familiar with the subject that any purchaser contemplating the installation of an electric plant would not only save a great deal of his own time and be spared a great deal of annoyance, but would actually effect a very material saving in retaining our services to represent the interest of the purchaser.

Vol. IX. CHICAGO, AUGUST 22, 1891. No. 8

Electric Plant at Roebling's Wire Works, Trenton, N. J.

That the Roeblings appreciated from the start the great utility of the electric light is evidenced in the fact that as early as 1879 there was installed in their manufactory a Maxim lamp with one of the old type Maxim machines to supply current. As time went on this one light plant was followed by the introduction of a 45 light Brush dynamo and then came a small incandescent machine of 200 lamps' capacity. Unfortunately this somewhat primitive machine sparked badly at the brushes and a usurper was brought in in the shape of a Hochhausen 400 lighter. This last named machine, however, is not now operated with the other lighting apparatus. It has been removed and is now employed in what might be called isolated service in one of the shops where the number of lights are such as to require the machine's full duty.

In the place of this Hochhausen 400 lighter there was set up an 800 light United States 110 volt machine, and a short time after this was installed two Waterhouse 30 light arc machines for lighting the yards were put in, and these were followed last year by a Westinghouse alternating current 40 light arc, 2,000 candle power machine for lighting the wire mill. In the winter time all of these machines with the exception of the old Maxim and the 200 lighter are running every night, and in the summer it is the usual practice to run all except one of the Waterhouse machines.

Such is the lighting apparatus now employed at the factory in Trenton, and the reader will obtain a good idea of the general appearance of the dynamo room from Fig. 1.

A close inspection of the illustration just referred to will reveal the fact that the John A. Roebling's Sons company has gone still deeper into the refinement of methods than might appear at first glance.

Those familiar with such machinery will detect in the center of the cut a Thomson generator for welding service. The Roeblings claim the distinction of having installed the first wire welder turned out by the Thomson Welding company. With this plant ⅜ inch iron could be welded. The machine used was of the direct type, that is, with the dynamo embodied in the welder proper, and ran successfully for more than a year, making in its lifetime about 370,000 welds. The Roeblings were so well satisfied with its performance that the generator shown in the illustration of the electric light station and seven small welders were contracted for. It may be mentioned that the first welder is not worn out, but merely superseded on account of the greater convenience of the new type machine.

From Fig. 2 there can be obtained an excellent idea as to the manner in which the welders are set up in the Roebling works. The cut shows two of the seven machines now in service. Between the welders is the small wheel employed to reduced the burrs formed in welding the wire.

The WESTERN ELECTRICIAN is indebted to F. A. C. Perrine, electrical engineer for the Roebling company, for information relating to the welding and lighting plant. The photographs are the work of Mr. Cabazola, also with the Roeblings

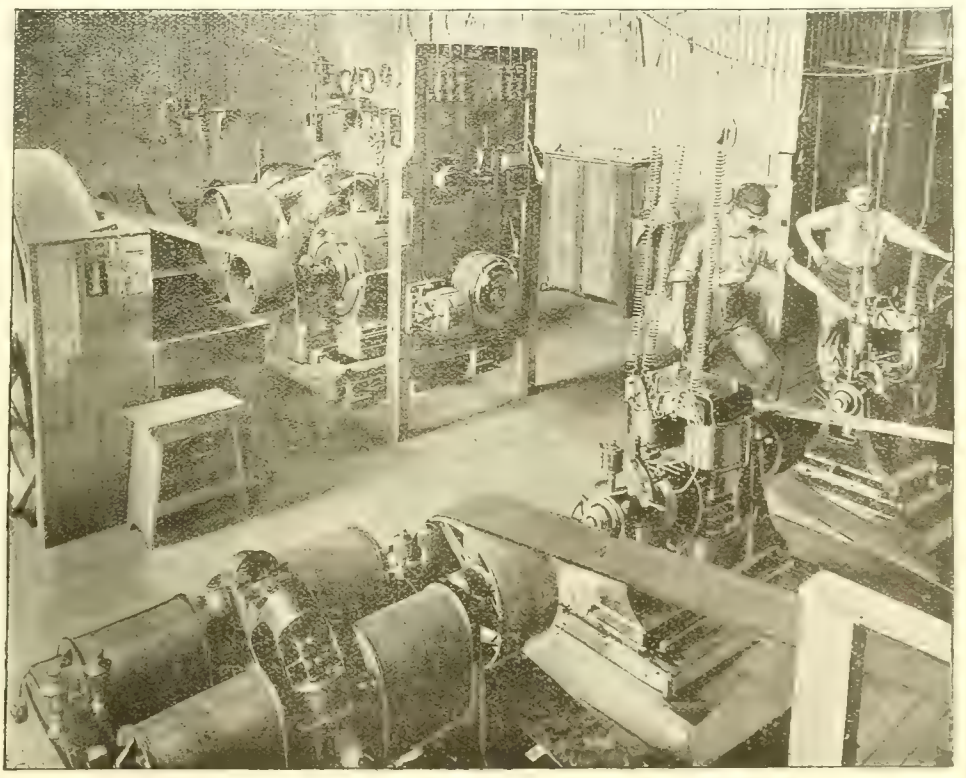

FIG. 1 ELECTRIC PLANT AT ROEBLING'S WIRE WORKS, TRENTON, N. J.

Electricity at the World's Fair.

Apparently no progress has been made in adjusting the misunderstanding between the departments of electricity and construction. The latter has been in stormy water of late, owing to the resignation of Chief Engineer Gottlieb and the subsequent cessation of operations on all the buildings now in process of construction at Jackson Park. For several days last week not a stroke of work was done on any of the buildings, including that intended for the department of electricity. On Monday last building operations were again resumed.

A sensation was caused by the announcement that work had been stopped, and the department of construction was subjected to much unfavorable criticism. It was stated in explanation that it had been discovered that Mr. Gottlieb's calculations of the strains to be put upon the foundations of the buildings were incorrect and that heavier timbers would have to be substituted for those originally laid down in order to sustain the heavy machinery in most of the large buildings. The public was led to infer that the discovery of this serious error led to the chief engineer's resignation. While the new figures were being made all work was suspended. This state of affairs engrossed the attention of the directors and the committee on grounds and buildings to such an extent that nothing was done in relation to the controversy between the committee on electricity and the electrical department on the one hand and the department of construction on the other. It is asserted that the engineers' errors and the changes to be made will cost the exposition company between $200,000 and $300,000.

Another criticism of the department of construction was in relation to the plans for the buildings. A great many of the plans are drawn to a scale of one-thirty-second of an inch to a foot. This, the contractors complain, is too fine. [illegible] could get along with the specifications while laying foundations, but were unwilling to let large mill orders for the finer work when the variation of one-thirty-second of an inch [illegible] foot in the timber. Some of the specifications are drawn to a larger scale, but it is claimed there is a general lack of satisfactory details.

The principle for which Chief Barrett has so long contended—that the chiefs of departments should have charge of the machinery installed on the fair grounds for actual use, in connection with the exhibits—has pervaded other departments, and is the subject of general discussion. The situation in the machinery department is precisely analogous to that in the department of electricity. Many of the directors think that Chief Burnham ought to be empowered to buy the big engines that will be used to furnish power in the [illegible]. Director-General Davis believes that the chief of machinery, [illegible] ought to be allowed to get the motive power free, as a part of the exhibit. That is what President Palmer and other commissioners think, and they have advised Colonel Davis to select his chief at once for that department. "I have my man ready to name [illegible] will make the nomination very soon," the director-general is reported as saying. "I am only waiting to make sure of his confirmation."

The [illegible] states the case clearly as follows:

If the exposition directors were to buy the machinery outright it would cost them considerably more than $1,000,000. To avoid this expense it has been suggested that the manufacturers would be glad to furnish all the necessary machinery free for the privilege of exhibiting the engines and other machinery running.

Right here is where the hitch comes. The director-general and department chiefs have exclusive control of all exhibits. If the directors secure the machinery as exhibits, they cannot install the plant without permission from the director-general. If this permission were refused, the directors would be compelled either to abandon control of the power plant or else pay the million or more it would take to purchase it.

Director-General Davis insists that the construction department should designate the amount and kind of power that will be needed and let the department chiefs secure it as exhibits. While the director-general has been trying to get this question of jurisdiction settled, Chief Burnham, presumably by consent of the directors, has gone ahead and practically completed negotiations for all the machinery to be used for power. But he cannot put in his machinery until the commissioners and directors agree on terms, and so the power arrangements are delayed until the question is settled.

"It may cost the directors $1,000,000 to learn what our rights are," said one of the commissioners. "They have apparently handed the construction and government of the fair over to Mr. [illegible]. I [illegible] Mr. Burnham personally, but I don't like his autocratic methods a little bit. He seems determined to control not only the building work but the executive departments of the fair as well. [illegible] him he will have more respect for the act of congress which gives us our authority, and [illegible] will have a less exalted idea of his ability to dictate to the national commission. [illegible]

they will put the brakes on Chief Burnham and give the director general the power that belongs to him by right."

On Monday afternoon the national board of control considered the question of authority as between department chiefs and D. H. Burnham, chief of construction. It adopted the following resolution:

Whereas, It has been represented to this board by the directory of the World's Columbian Exposition that a very large saving may be effected in that branch of the work of

FIG. 2. ELECTRIC PLANT AT ROEBLING'S WIRE WORKS, TRENTON, N. J.

construction which relates to the supply and distribution of the adequate power, light and heat essentially necessary for the suitable equipment of the buildings to be devoted to exposition purposes, provided the owners of boilers, engines and machinery or other appliances which may be secured for that exclusive purpose by the said directory of the World's Columbian Exposition shall not be, on account of the primary devotion thereof to such utilitarian purposes, precluded from entering such boilers, engines, machinery and other appliances as competitive exhibits within the several classes to which they shall respectively properly belong, and this board has been requested to take appropriate action in this behalf; and,

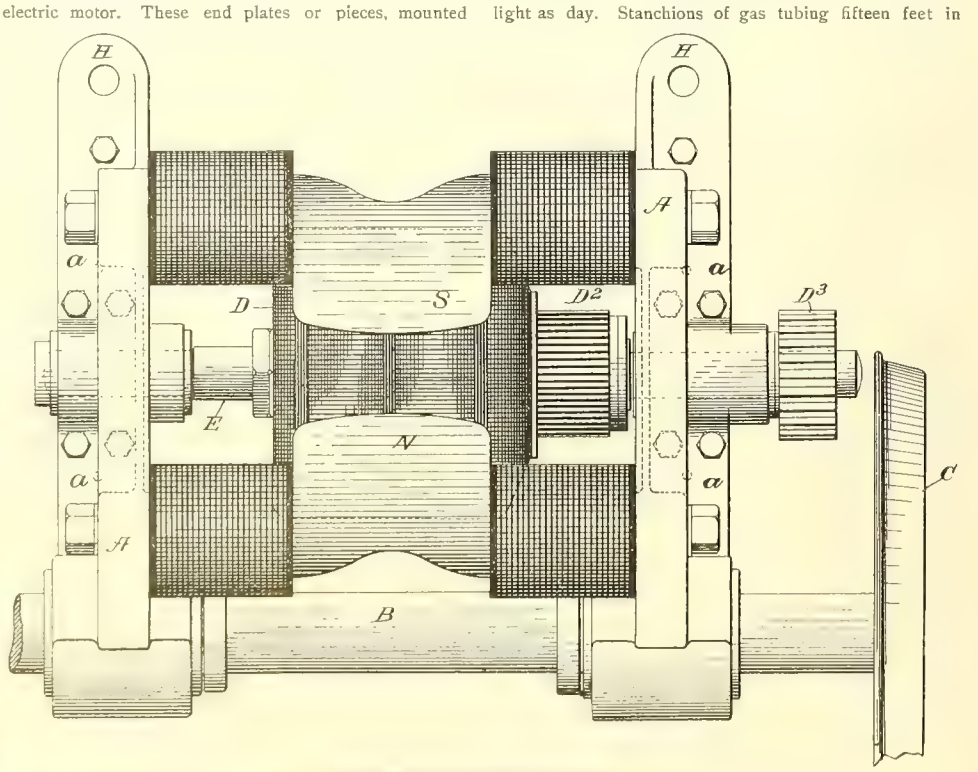
Whereas, This board recognizes that the duty and responsibility of the work of constructing and furnishing suitable buildings, adequately equipped for exposition purposes, rests exclusively upon said World's Columbian Exposition, subject—when completed and tendered—to the right of acceptance by the national commission, and this board is therefore unwilling to assume responsibility in any degree in such work of construction, or to authorize any department or agency subject to its authority to do so; therefore, be it

Resolved, That it is the judgment and opinion of this board and it hereby—in so far as it may lawfully do so—declares that the fact of such boilers, engines, or other machinery or appliances as shall be procured and located by the directory of the World's Columbian Exposition and be by them devoted to the supply and distribution of adequate power, light and heat for the exposition buildings shall not preclude the entry of the same by the owners thereof as competitive exhibits in the classes to which they may severally belong, subject, however, as to the classification and installation thereof, to the rules and regulations prescribed by authority of the national commission.

The *News* prints its account of the meeting under the heading "Burnham is Not Boss," and gives an interview with Commissioner St. Clair as to the effect of the resolution. "It means," said Mr. St. Clair, "that neither the [illegible] will have exclusive con[illegible]. The director wanted us to give Mr. Burnham authority to get machinery free as exhibits [illegible] the power to delegate [illegible] get manufacturer to let [illegible] for power, but cannot [illegible] the chiefs of machinery and electricity agree to accept them. [illegible]

The Mailloux Electric Motor.

In the general construction of electric railway motors it is necessary to lift the armature out of its bearings and remove it from the machine for repairs or examination. This method is often attended with considerable difficulty. In the accompanying cut is shown an arrangement devised by C. O. Mailloux of New York, by which this trouble may be avoided. The motor frame is made in two parts, one of which is supported upon the car axle of the truck frame, while the other, upon which the armature rests, may be lowered with the armature, leaving the main portion of the motor undisturbed. The field magnet frame is also divided into two parts, the lower one being removed with the armature, leaving the upper portion in its usual position. In the cut *B* indicates the axle of the car and *C* the wheel fixed to the axle in the usual manner. *AA* represent the end plates or pieces of the field magnet frame for the electric motor. These end plates or pieces, mounted



THE MAILLOUX ELECTRIC MOTOR.

[illegible] one to the other, are provided with suitable journal-[illegible] for the armature shaft, and are mounted upon the car axle by sleeving the yoke pieces upon it. They are each made in two parts and are connected by the four parallel cross rods or bars which support the four field magnet pole pieces of the machine. The cross rods or [illegible] and are utilized as a part of the field magnet or field magnet circuit, in which case the field [illegible] upon the cross bars or rods [illegible] if [illegible] of magnetic yoke pieces.

D indicates the armature of the motor and *E* the armature shaft. D^2 indicates the commutator cylinder. There is a gear-wheel at D^3 which is employed as the first gearing for rotating the car axle by the armature. Each of the yoke or end pieces *A* is made in two parts, and each is provided with flanges *a* at the line of union, where the two parts may be secured by means of bolts.

The armature shaft of the machine is mounted in the end plates *AA* parallel to the car-axle, as shown, the journal bearings for the shaft being formed on or carried by the plates at or near the center, which is connected with the peripheral thicker portion of the end pieces by flanges *a* and by webs. These webs and the other parts forming the interior portion of the end pieces form a protection against injury to the armature at its ends. Each end plate *A* is enlarged to form a suitable oil box or cavity, and its upper portion is extended, as at *H*, to form a nose-piece, which may rest by a spring or other bearing upon a cross-bar of the truck frame in the manner usual in the art. At its opposite side it rests upon the top of the car-axle, while the lower part, which may be detached from the upper, is provided with a part of the sleeve surrounding the axle. The remaining portion of the sleeve is formed by the detachable cap, like a journal cap, which may be bolted to the parts of the sleeve or journal-bearing which surrounds the car-axle, and are carried by or formed upon the two portions of the bisected end plate *A*. When it is found necessary to remove the armature the car may be run over a pit and the bolts fastening the upper and lower parts of the frame *A* removed, when the lower portion can be lowered with the armature in place upon it, the upper portion resting upon the car-axle and the truck frame. The flanges *a a* are provided with a dowel or guide-pin and guide opening, as indicated, where the lower part may be guided into place when it is to be secured to the upper part. It is possible to attach the lower part of the yoke pieces with the armature shaft in place and fix them in position before applying the cap to complete the sleeve or journal bearing around the car-axle.

Working by Electric Light.

On Aug. 14th work was begun on the pipe laying of the Economic Fuel Gas company on Dearborn street, Chicago. Electric lights about seventy-five feet apart swung over the heads of the workmen and made the street almost as light as day. Stanchions of gas tubing fifteen feet in height were placed at either side of the ditch, the top of the supports coming together like a trestle, and upon these the electric light wire was strung. One end of the wire was then attached to the conductor in a conduit at Dearborn and Harrison streets. The men worked with even greater rapidity than in the daytime for the reason that it was cooler and they did not get tired so easily. The present force of men will be augmented by an additional 500. All of the work of the company north of Van Buren street will be done at night, as the traffic in daytime would be seriously obstructed.

Photochronograph.

The application of electricity to scientific researches and observations is attracting more attention than is generally supposed by those who are not entirely engaged in purely scientific occupations. The accompanying cuts illustrate a device in which the electrical arrangements form a unique feature. It is the invention of the Rev. George A. Fargis, S. J., assistant director of the Georgetown college observatory. The device is known as the protochronograph and is employed in astronomical obser-

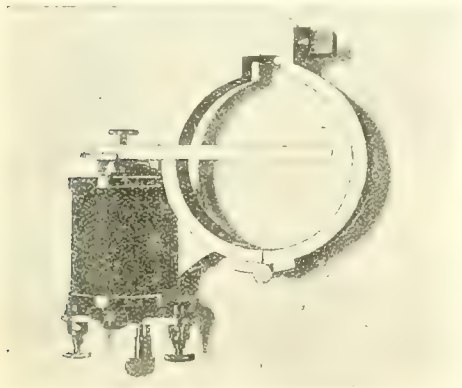


FIG. 1. THE PHOTOCHRONOGRAPH.

vations. For many years experiments have been made with the view of applying photography to this line of work, but there have been many difficulties experienced and but little progress has been reported. The chief defects in the systems heretofore applied have been found in the motion of the sensitive plate, the weight of the moving parts and the resulting uncertain rate of the battery, a photographic parallax, owing to the distance of the sensitive film from the wires and the partial obliteration of the star trail in photographing the wires. Of these serious drawbacks the motion of the plate proved the most troublesome. It was finally decided that the plate should not move and the invention of the occulting-bar followed

During the last year Prof. Fargis has been conducting a line of independent experiments at the observatory with which he is connected and these have resulted in the development of the photochronograph shown in the cuts.

The new apparatus shown in Fig. 1 consists of a strong brass collar, fitting closely to the sliding tube, just behind the collimating plate, by means of a hinge and screw-bolt. To this collar is attached a U-shaped soft iron core, with a coil on one of the arms. The naked part of the core is bent back and up, so as to act on the armature from behind. The end of the core is encircled with a thin ring of cork, to diminish the force of the armature stroke. The usual adjusting and connecting screws are conveniently placed. A strip of steel about two millimeters in width and two-tenths of a millimeter in thickness is soldered to

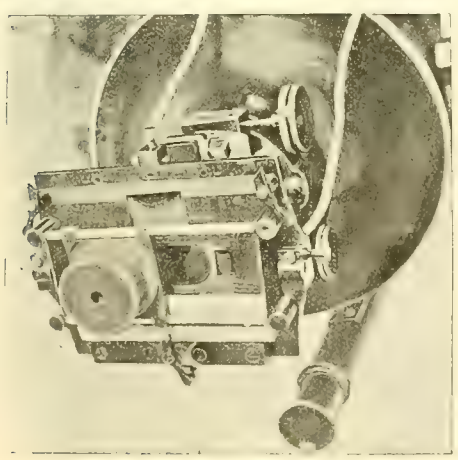

FIG. 3. THE PHOTOCHRONOGRAPH.

the armature at right angles to its line of motion. This is passed through the apertures in the side of the focusing tube intended for direct wire illumination, and stretches across the reticle. The coil, armature, and occulting-bar or shutter are so fixed to the collar that, when at rest, the lower edge of the shutter (clamp east and transit pointed south) is parallel to and a fraction of a millimeter above the horizontal diameter of the reticle. Fig. 2 shows its position on the transit.

The plate holder is merely part of the Ertel micrometer box. The outer plate, carrying the eye-piece, the one next it with the movable wire, and the micrometer screws were removed from the box, together with the set of beveled brass strips which formed the upper grooves, leaving only the plate containing the fixed wires and the one holding the collimating screws. To the outer surface of the latter are attached horizontally, immediately over and about eight millimeters from it, two parallel steel bars holding the eye-piece in a sliding frame so as to command a view of the whole reticle cavity, Fig. 3. The sensitive plate is inserted inside the parallel bars so as to rest flat against the reticle, and is held in place by a wedge of soft wood. When the wires are photographed by the object-glass illumination their images and that of the star are practically in the same focus, so that the thickening and displacement which constitute the photographic parallax are avoided.

For the necessary purpose of identifying the clamp side of the negative, an arbitrary mark, in the present case a minute drop of ink, is placed upon the reticle, on that side. This is printed on the negative when the wires are photographed, and the identification is complete.

Suppose, then, that connection be made with the sidereal clock relay, and that a star begins its transit. When the current is turned on, the shutter falls with the armature, cutting off the light of the star. At the break the shutter rises with the armature, uncovering the star for one tenth of a second, and dropping again as the current flows. Hence the negative shows a simple line of dots, each representing one-tenth of a second exposure. The clock contact may be changed so as to avoid breaking the contact at any time desired. Any second can, therefore, be readily identified. The oval blackened form shown in Fig. 4 is the glass reticle, photographed by the light of the object-glass, and the white band across the center is made by the shutter, which intercepts this light when the wires are being photographed thus preserving the star-trail from obliteration. This is accomplished by disconnecting the clock-relay and turning the current on directly to the apparatus. This holds the shutter down, right across the path just made by the star, completely protecting the photographed transit.

It might be urged that the armature stroke would impart a tremulous motion to the instrument, owing to the manner in which the apparatus is attachd to the focusing tube. But Prof. Fargis announces that the careful micrometric measurement of over 200 photographic transits shows no perceptible trace of any such error, and, if it were so, a very obvious arrangement would permit the application of this method, by a mere juxtaposition of the apparatus to the transit.

In this manner the objectionable features, which led to the rejection of the apparatus as at first constructed, would seem to be eliminated. The sensitive plate does not move from the beginning to the end of the operation, and, being securely wedged in against the reticle, there is little cause to fear photographic parallax. The extreme lightness of the occulting-bar and the simplicity of the armature movement, doing away with all transferrence of motion, reduces friction to a minimum, and makes the clock-beat and shutter movement practically synchronous. The complete protection of the star-trail against the illumination necessary for photographing the wires, as just described, is also a distinctive feature of this method. For these reasons, it may be conceded that the instrument described has a valid claim to the name of "photochronograph," since it actually registers on the sensitive plate the time of the transit of a star.

The battery is composed of four Daniell cells for the photochronograph and one for the sidereal clock-relay. An extra battery of four cells is in readiness in case the first

with three wires running under the floor from the switch-

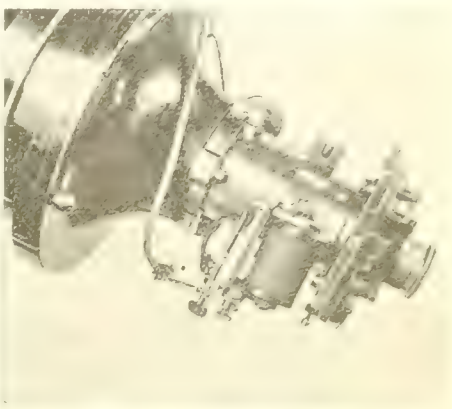

FIG. 2. THE PHOTOCHRONOGRAPH.

forming two loops at the command of the operator. The switch is conveniently situated near the transit pier, and so arranged that on one point the sidereal clock-relay and the photochronograph work as described; by the second the current is turned to the photochronograph alone, or by dropping the lever between the two points both currents are broken. This last is, of course, the usual position between the observations

The operation of the device is thus described by the inventor. The instrument is set on any star about to cross the meridian. The current is switched on to the sidereal clock, and an eye observation is made of the working of the photochronograph. This is of prime importance, excluding as it does all doubt as to its actual performance during the observations. No field illumination is used. By means of the sliding eye piece the eye of the observer takes the place, for the nonce, of the sensitive plate, and the working of the shutter is carefully observed. The star image, though blurred from being out of visual focus, is sufficiently distinct for the purpose. The successive appearances and disappearances of the star are regulated with the slow motion screw; care being taken that the appearance is unmistakable, the disappearance complete, and this for the whole course of the transit. This operation affords the observer a striking illustration of his personal equation. For the armature beat at the appearance and disappearance of the star enables him to appreciate the slowness of the retina in receiving and losing the star

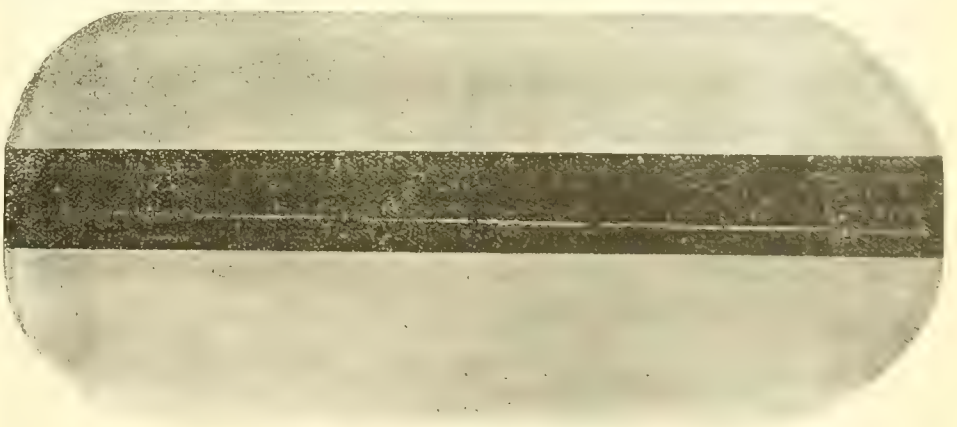

FIG. 4. THE PHOTOCHRONOGRAPH.

image; reminding him that the star is not seen where it actually is, but where it was [illegible] way of parenthesis. The shutter once [illegible] everything is supposed to be ready for a photographic [illegible]

The transit instrument is now set on the star and clamped. By means of the finder the star is [illegible] until by its position on the vertical wire, it is seen to be on the point of entering the field of the reticle. The current is then turned on at the switch, the [illegible] to the west side of the reticle, and with the [illegible] the star is adjusted to the armature edge of the [illegible]

for a one-tenth second exposure, and to the other edge, if a nine-tenth second exposure be desired. This settled, the plate is slipped in flat against the rettcle, the wedge pressed in between the back of the plate and the parallel bars, and the bag securely fastened.

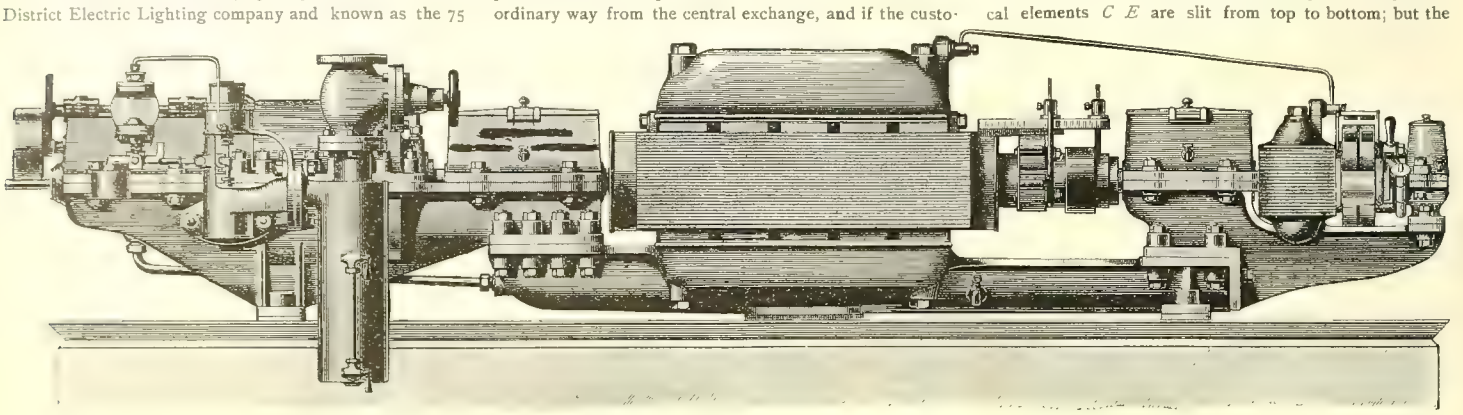
The time of passage across the reticle varies, of course, according to its size and the declination of the star. In the present instance an equatorial star takes four minutes to cross.

The transit over, the clock circuit is broken and the current turned on to the photochronograph alone. This brings the shutter down and protects the star trail while the wires are photographed. The transit instrument is unclamped, tilted to a convenient position, and a light is held to the object-glass. This done, the current is broken, the plate removed and placed in the box prepared for it.

It may be well to remark that the slight irregularity of star trail in the beginning of the transit, as shown by three or four of the dots in Fig. 4, is owing to the fact that the occulting bar was already in motion before the sensitive plate had been adjusted to the plate holder.

Parsons' Steam Turbine Dynamo.

In the accompanying illustration is shown an English steam turbine alternator employed by the Newcastle and District Electric Lighting company and known as the 75

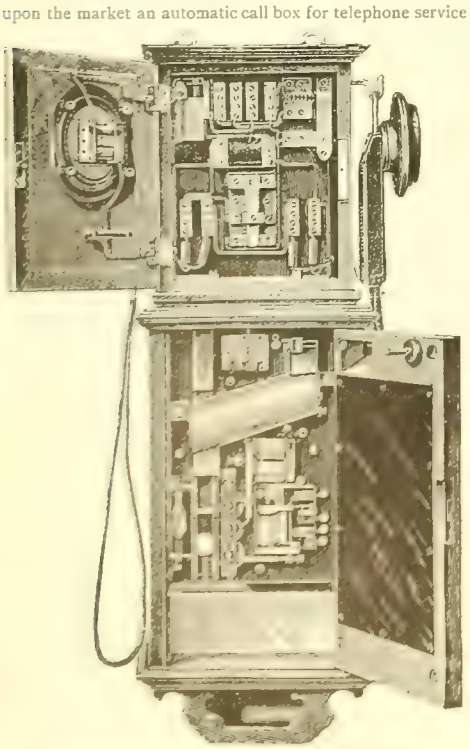


PARSONS' STEAM TURBINE DYNAMO.

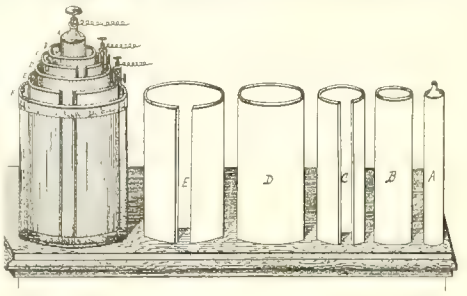
unit alternator. These machines are made to operate at 5 000 revolutions per minute. Four machines are now employed and the demand for electric light has been so great that the station is being enlarged after eighteen months' operation. The capacity of the plant will be 10,500 ten candle power lamps. The cut is reproduced from *Electric Plant.*

Automatic Pay Call Box for Telephones.

A Berlin manufacturer announces his readiness to place upon the market an automatic call box for telephone service



through the usual arrangement for testing with regard to diameter, thickness and weight and it will then pass to a pair of grooves, which are movable upon a hinge. Here its progress is arrested by the upper of three wheel segments, which, protruding into the side of the grooves, and actuated by the armature, of an



THE POUDROUX BATTERY.

electro-magnet, form a check arrangement. Just before reaching this point, the coin has pressed a small projecting lever, thus making contact and allowing the bell to be rung when the black knob in front of the telephone instrument is pressed. The call is answered in the ordinary way from the central exchange, and if the customer is informed that for any reason the required communication cannot be obtained, he has only to press the white stud, when the movable grooves, are thrown forward, releasing the coin from the check arrangement, and allowing it to fall to the refunding box. Should, however, the desired connection be made at the exchange, the current passes through the magnet, attracting the armature with a force sufficient to overcome that exerted by the spring. The coin thereupon falls to the fixed pair of grooves, and is arrested by the segment.

Here it remains until the signal at close of conversation is given, when it is again released by the magnet, and allowed to fall into the cash box, pressing *en route* a second lever, which, being connected diagonally with replaces it, and at the same time breaks the contact. This lever is of such a length that a coin passing to the refunding box presses it, replacing it and breaking contact as if at close of a conversation.

Should, however, the closing signal be omitted, it is obvious that the coin will remain at the grooves. In order to prevent loss from this cause a lever, connected at one end to the armature and terminated at the other by a small roller projecting into the slot, is provided. By this means the armature is moved, as if electrically, upon insertion of the next coin, and the one remaining in the instrument has fallen into the cash box before the other has passed through the testing arrangement. The cut is reproduced from the London *Electrical* [illegible].

Underground Conductors in Paris.

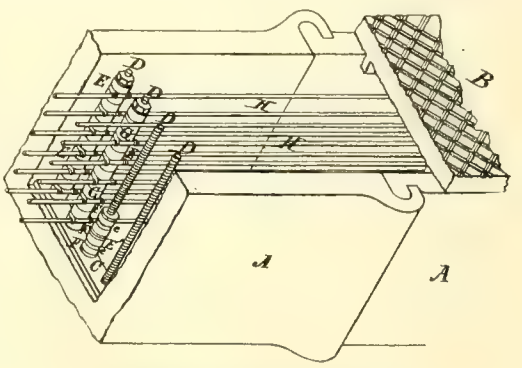
A brief description of the underground system for electric lighting in Paris was presented in the WESTERN ELECTRICIAN of Aug. 8th. The method of arranging the wires in the conduit, which was illustrated and described, appeared to be the principal feature of the system. An American inventor, W. E. Banta, of Springfield, O., [illegible] the system as his invention, and in support of this a [illegible] patents granted him June 27, 1882, and May 19, 1885. A drawing forming part of the specifications in the former patent is reproduced herewith, showing the same general appearance of the subway and method of [illegible] the wires on posts, as that employed in Paris. In the letters patent granted Mr. Banta, the system employed in Paris is described in detail. The application for the patent was filed Nov. 2, 1881.

Poudroux Battery.

Flavien Poudroux of Paris claims to have "solved the long-existing problem of a substitute for dynamos in electric lighting by providing a cheap, inodorous, inoffensive electric battery capable of supplying light enough for domestic uses." In the accompanying illustration a view of the battery and duplicate parts is shown. Mr. Poudroux claims that by the construction of this battery he is enabled to employ a great surface of zinc in a cell of moderate capacity containing little liquid. The ingredients of the solutions, he adds, are very cheap. One charging of the battery will suffice to fit it for working at least one hundred and eighty hours, excepting the liquid within the cell *D*, which should be renewed every thirty hours.

The battery is thus described: *A* is a carbon cylinder, which forms the center of the battery, to which a wire is attached; *B*, a porous cell or partition surrounding the cylinder *C*, a hollow cylinder of zinc similarly surrounding the cell or partition and having a wire attached to it; *D*, a porous vase or partition in like manner surrounding said hollow cylinder *C*; *E*, a hollow carbon cylinder having a wire attachment and also surrounding the cell or partition *C*; and *F*, the external glass vase or jar which surrounds the carbon cylinder *E*, and being provided with a bottom contains the operative parts of the battery. The cylindrical elements *C E* are slit from top to bottom; but the cylindrical cells or partitions *B D* are left with solid walls.

The space between carbon element *A* and partition *B* contains a depolarizing aqueous solution consisting of azotate of potash, binoxide of manganese, bichromate of soda and sulphuric acid in the proportions, by weight, in the order named, of two-twentieths, one-twentieth, three-twentieths, and two-twentieths of the water employed. In the space immediately surrounding the zinc element *C* and within the cell or partition *D* is a liquid excitant consisting



UNDERGROUND CONDUCTORS IN PARIS.

of an aqueous solution three parts, by weight, of chlorhydrate of ammonia and two of azotate of potash to twenty parts of water employed. In the space surrounding the carbon cylinder *E* is another depolarizing solution of bichromate of soda acidulated by one-tenth of its weight of sulphuric acid.

In addition to the advantages noted, the inventor of this battery claims that it "creates in each element two distinct and constant currents, which are utilized in giving an energy hitherto unknown."

An electric plant intended to supply 4,000 incandescent lamps is being installed at Alicante, Spain. Power will be given by Otto gas engines supplied with Dowson gas. This is the first instance in Spain of a large power being produced by gas engines, the gas being made in the neighborhood of the engines. It seems probable that the use of gas engines will increase, especially at Madrid, as smoke abatement has now become an important question in that city.

Electric System of the Buffalo Street Railway Company.

One cannot but be impressed, after a visit to the station of the Buffalo electric street railway, with the idea that if all electric roads were built and equipped as this has been there would be no opposition to, but rather a universal sentiment in favor of, electrical power in street car work.

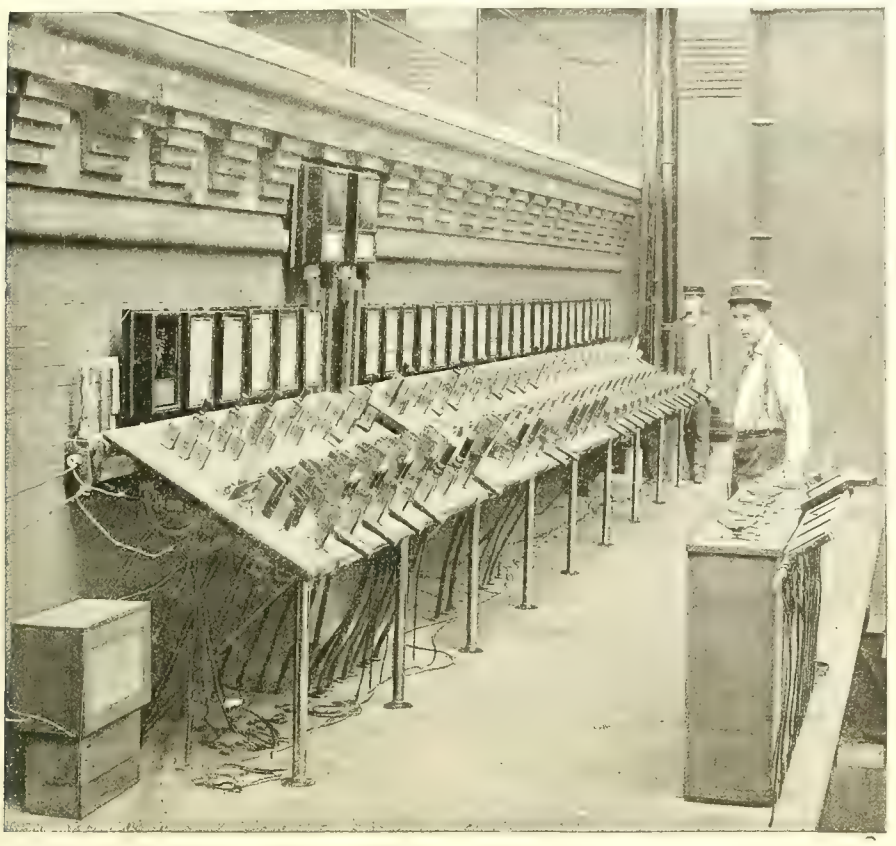


FIG. 2. ELECTRIC SYSTEM OF THE BUFFALO STREET RAILWAY COMPANY.

On July 1st the cars on the first line of the converted system of the company were started. This portion of the system included the Niagara street and Forest avenue lines. It was the first sixteen miles out of one hundred miles which are being equipped electrically, but about forty miles of the system are expected to be in operation during this season.

The Buffalo railway system is owned by a syndicate which controls the largest amount of street railway property in the country, including lines in Newark, Paterson, Rochester, Pittsburg, Louisville and other places.

The power station, interior views of which are shown herewith, is one of the largest in the country, and will, when completed, have a capacity of about 5,500 horse power.

The present installation, Fig. 1, consists of three engines of 250 horse power each, made by the Ball Engine Co., Erie, Pa., and two vertical compound engines of 500 horse power each, built by the Lake Erie Engineering Works, Buffalo. The last mentioned engines are improved forms designed to occupy the field between the Corliss and high speed engines. They are especially constructed for direct belting or direct shaft connection. The large engines are each to drive two 200 horse power Edison generators, and the smaller ones one each. The boilers are the Babcock & Wilson sectional water tube type set in two batteries of two each. Everything is arranged in duplicate, to provide as far as possible against any break-down. The power room is 86x140 feet, with an iron truss roof spanning the whole. There is provided a ten-ton traveling crane for handling the engines and dynamos. This is operated either by hand or electric motor.

The switch-board, as will be seen from Fig. 2, is one of the most complete that has ever been introduced for railway work. It has several novel features. On the front of the gallery will be seen the regulator boxes for controlling the dynamos. In the rear is located the dynamo switch-board proper carrying the switches, ampere meters and main bus ampere meters. Further along on the back are the feeder switches and feeder ampere meters, each feeder having a separate switch and meter. A particular feature of this switch-board is the use of two "bus lines," so that two different pressures may be had if it is desired to distribute to the lines of a territory with outlying districts. As this station feeds a radius of seven or eight miles the value of this arrangement will be understood. All feeders from the station are underground cables laid in conduits. The local distribution to the trolley wire is, of course, overhead, the underground system.

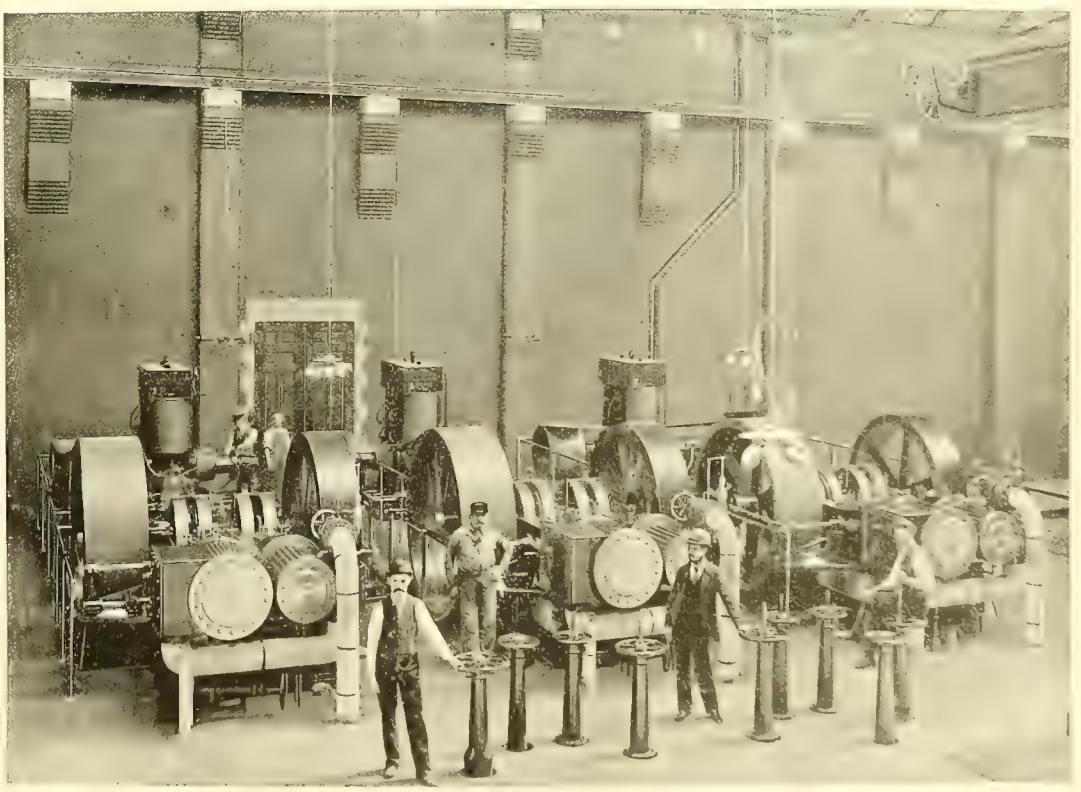

FIG. 1. ELECTRIC SYSTEM OF THE BUFFALO STREET RAILWAY COMPANY.

line.

The cars, as already stated, were first started on July 1st, after a trial the evening before, and have operated successfully since. [illegible] fifty cars on this [illegible] operation. The system will be extended until it comprises about [illegible] miles of [illegible] intention is to equip the entire system with electric motors as rapidly as possible.

The Field Engineering [illegible] engineer and electrician for the Buffalo system, as well as that in Newark and Paterson. The work at Buffalo is in charge of Engineer J. B. Craven, who has been very energetic in pushing the construction in all its numerous details. The planning of the system was done at the New York office of the Field company, under the direction of the engineering staff, C. J. Field, E. F. White, E. J. Cook and F. Beurre.

The officers of the Buffalo Railway company are Henry A. Watson, president; H. M. Littell, vice-president and general manager; Edward Edwards, general superintendent. The cuts showing the dynamo and engine equipment and the switch-board are taken from the *Street Railway Journal*.

A Key-Hole Circuit.

In a United Press dispatch dated at Hartford, Conn., is given the following account of the alleged misdeeds of a street railway electrician: "George A. Waddell, of New York, was recently employed as electrician by the H. & W. street railway. He did not get along well with Superintendent Shepard. Last week Waddell built a room about twelve feet square in the car house and put up a sign to the effect that this was his laboratory, and the superintendent was ordered to keep out of the room, as well as everyone else. Mr. Shepard had a key to the room. On Saturday afternoon Mr. Barrett, of the Barrett Storage company, heard Waddell say to a man that if the superintendent tried to get into his room again he'd get something he wouldn't like. Mr. Barrett made an investigation and found that Waddell had rigged up a [illegible] circuit through the keyhole of the door, so that as soon as a key was inserted the person [illegible] would receive a shock of 500 volts. Waddell asserted that he meant no serious injury. He was discharged and has left the city."

[illegible] last week was [illegible] papers on interesting topics were [illegible] for publication. The Edison [illegible] to the electrical papers from the official stenographer's minutes. This year, however, the report was withheld for the [illegible]

WHEN a temporary committee, organized for the purpose [illegible] its correspondence, we may expect that all its work of

---

is entirely correct. The Canadians are outdoing themselves to show every attention to the visitors, and the members of the association should show their appreciation of these graceful attentions by making the convention the largest and most successful in the history of the organization.

AN exchange calls attention to the fact that the question of securing rapid transit for New York is being handled in a unique manner by the daily papers of New York city. The *Sun*, for instance, which is supposed "to shine for all," dwells on every trivial accident connected with the underground system of London and passes lightly those which occur on the "L" roads in Gotham. The *Sun* is certainly outspoken in its opposition to the underground system, but its present policy is nevertheless at variance with its position on other subjects, where its fearlessness has won the admiration and respect of its bitterest foes.

REPORTS from the Frankfort electrical exhibition indicate that American interests are rather scantily represented. This is undoubtedly due to a great extent to the fact that the electrical fraternity in this country is husbanding its resources for the World's Fair in 1893 when it intends to put its best foot forward in handsome fashion. This does not prevent a hearty interest in the German exhibition, however, nor a cordial desire to see it completely successful. The outcome of the experiment in long distance transmission, especially, is awaited with the confident expectation that it will materially contribute to the development of this important branch of electrical science.

A NOVEL method of displaying exhibits has been adopted by the committee of the American Street Railway association for the Pittsburg convention. It has been decided to arrange the exhibits on a double-deck excursion boat moved to the wharf near the headquarters of the convention. The last convention of this association was devoted largely to the consideration of electrical matters and was in a large measure an electrical convention. This year it is anticipated the electrical interests will assume even more prominence, and the displays will be more elaborate. There will be ample opportunity to examine the operation of the several systems of electric railways and compare them with the cable system.

ONLY a short time ago the WESTERN ELECTRICIAN published an account of the manner in which a hose-cart was whisked to a fire in a Chicago suburb by being atttached to an electric car. Out in Omaha electricity has been put to even a queerer use as a motive power. A house was being moved along a street in which the tracks of the electric line were laid, and in order to get it out of the way as soon as possible the superintendent of the road made fast an electric car to the building at night and hauled it comfortably to the top of a hill which had proved a formidable obstacle. The spectacle presented by a house pursuing its ponderous course on rollers, in tow of an electric car, must have been very droll, but the practical aspect of the incident will commend itself at once to all who have been subjected to the annoying street blockades caused by these tortoise-like obstructions.

RECENTLY the announcement was made that the electric lighting companies of Minneapolis would soon place their wires under ground. The telegraph companies were also expected to bury their cables, but it was feared that they would refuse to do so until the other companies complied with the city ordinance relating to this matter. In fact, a prominent official of the Western Union company was reported as expressing the opinion that the telegraph companies would consider the matter when the electric light and railway companies had taken steps to comply with the law. Now, however, the statement is made that the Western Union company will voluntarily bury its wires and that it will go about the work at once and push it to a speedy completion. The announcement has been received with much favor in Minneapolis. That city will soon have the distinction of having more underground work proportionately than any other city in the country. It has already gained distinction from the fact that it has one of the most complete as well as extensive electric railway companies in [illegible] will gain fresh laurels in the electrical world.

[illegible] Exposition reached an interesting point during the last week. Chief Engineer [illegible] owing to a difference of [illegible] himself. Work was temporarily discontinued on Mr. Gottlieb's retirement and *it* is understood that several important changes will have to be made in the plans. It is certainly to be regretted that there has been so much friction between the several departments of the exposition, and the present instance has served to bring the matters prominently before the public. The directors and commissioners have been obliged to take action in the matter. The dispute between the chief of the construction department and the chiefs of the departments of electricity and machinery was the topic discussed at a meeting last Monday. The result was practically a victory for the latter, as their claims for recognition in the matter of introducing apparatus were recognized. It is to be hoped that the heads of departments will be able to reach a satisfactory arrangement with Chief Burnham, but it is also to be hoped that they will not sacrifice the interest of their departments to the whims of the construction department. They should be the best judges of the machinery to be installed, and their approval of all apparatus and machinery employed should be demanded.

THE disposition of fire engineers to gain information as to the best manner of handling wires conveying electric currents, shown at the national convention of fire engineers held in Springfield, Mass., last week, is entirely commendable. Electric companies are often subjected to needless expense and annoyance by the over zealous haste of firemen, who, it must be confessed, have usually a decided antipathy to electric wires. The electrical companies are willing to sacrifice their property promptly at any time when the public safety demands it; but in many cases, at fires, the wholesale cutting of wires is unnecessary, or at least can be deferred until a competent lineman can be sent for. Were fire engineers generally better acquainted with the fundamental principles of the commericial applications of electricity, excesses of this kind would occur rarely. In the case of fires arising from badly insulated wires, too, knowledge of this character would greatly aid the firemen in intelligently subduing the flames. Mr. Brophy is entitled to credit for his endeavor to diffuse useful information about electricity among firemen. He is severe, but to no greater extent than he should be, on defective insulation. His suggestion that persons reponsible for bad work should be held criminally responsible is interesting. If it could be impartially enforced, a law of this kind would undoubtedly have a salutary effect; but it is not difficult to foresee that many hindrances to its application would arise. For one thing, it would be no easy task to obtain competent inspectors at the salaries that cities would be willing to pay, and when large salaries were provided the offices would generally be filled by political parasites.

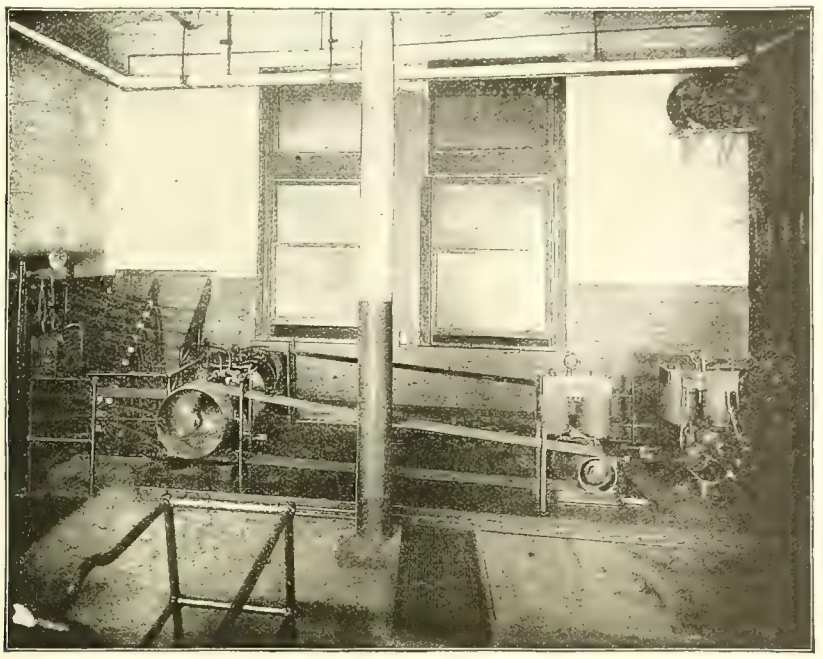
THE stirring days of the rebellion are vividly brought to mind as one reads the highly interesting address of W. R. Plum, president of the Society of United States Military Telegraphers, delivered at Washington, August 19th. The tributes to this important branch of the service have been numerous and hearty, and its usefulness is best summed up in the terse statement that during the war it constructed 15,389 miles of military telegraph lines, and sent 6,500 000 telegrams. Very many of the latter were of the utmost importance, and were transmitted under the most trying circumstances. Many stories of the courage and fidelity of the war-time telegraphers have been told to the admiration of thousands, but a far greater number of acts of real heroism and patriotism on the part of comparatively unknown operators have never been brought to public notice. The survivors of this honorable corps have just cause to take pride in their record, and they may rejoice in the assurance that their countrymen, recognizing the value of their services, will wish that the future of their organization may be as pleasant as the past has been useful and distinguished.

The telegraphers desire recognition as a component part of the army, and their claim seems to be a just one, and has been so held by nearly all of the leading Union generals. It is no half-hearted concession that the veterans seek, and should have. They desire certificates of honorable discharges from the army, such as will enable them to enter Grand Army posts. As Mr. Plum observes: "If it was justice to make officers of those in command of us, and honorably discharge them with increased rank, three months' extra pay and transportation home, while we who bore all of the casualities of the service, except in Captain Bruch's case, were dropped from the rolls at our posts of duty unhonored and unthanked, the query arises. Why, in times of peace, has our own government since established the military telegraph service as a coordinate branch of the army, and why has every civilized government on the globe done the same thing?"

We hope the telegraphers will succeed in obtaining long-deferred justice.

Interesting Motor Installation.

In the accompanying cut is shown a novel motor installation at one of the stations of the Edison Electric Illuminating company, Brooklyn. The plant consists of a 50 horse power C. & C. electric motor with two No 6 Edison dynamos. These are utilized to raise the voltage of the feeders in place of running the large station unit on the necessarily light load. The total efficiency of the entire plant taken on a run of twenty-four hours at full load, it is claimed, is something over 80 per cent. The plant is kept in operation day and night, as the dynamos are carrying a full load of 500 lights during the night and in the daytime are furnishing current to C. & C. electric motors ranging in size from 25 horse power downward.



INTERESTING MOTOR INSTALLATION.

The Montreal Convention.

The programme of the National Electric Light association convention has been nearly completed. The daily sessions of the convention will be from 10 A. M. until 2 P. M.

On the 8th of September the reports of the following named committees will be read and discussed: Committee on relations of manufacturing and central station companies, committee on data, committee on World's Columbian Exposition, committee on legislation, committee on underground conduits and conductors, committee on safe wiring.

On the 9th of September papers will be read and discussed as follows: Discussion of T. Carpenter Smith's paper, read at the Providence convention, on the "Distribution and Care of Alternating Currents;" W. C. Warner, "Various Forms of Carbons for Use in Arc Lamps;" Capt. Eugene Griffin, "Three Years' Deve'opments of Electric Railways;" H. Ward Leonard, "A Central Station Combining the Advantages of Both Continuous and Alternating Current Systems."

On the 10th of September there will be the reading and discussion of the following named papers: J. I Ayer, "Some Details of the Care and Management of an Arc Lighting Station as Practiced in the 'Municipal' of St. Louis;" C. J. Field, subject to be announced; George A. Redman, "Central Station Lighting by Water Power;" J. J. Burleigh, "Uniformity of Method in Keeping Central Station Accounts." An executive session will be held to elect three new members of the executive committee and to name the place of the next meeting.

Following is the programme arranged for the entertainment of the visitors by the citizens' executive committee of Montreal:

Monday, September 7th—3 P. M., opening proceedings of the convention in the Windsor hotel, address of welcome by the mayor and other distinguished members of the reception committee; 8 P. M., formal opening of the exhibition by his excellency, the governor-general.

Tuesday, September 8th—2:30 P. M., drive through the city and around the mountain; 8 to 11:30 P. M., conversazione at Redpath museum, Molson hall, McGill college.

Wednesday September 9th—2:30 P. M., fire department disp'ay on Champs de Mars; 5 to 7 P. M., garden parties; 8 P. M., banquet at the Windsor hotel.

Thursday, September 10th—2:30 P. M., through the kindness of the harbor commissioners, trip by boat down the St. Lawrence and the Lachine Rapids, stopping at the way at Caughnawaga, 5 to 7 P. M., garden parties.

Friday, September 11th—3 P. M., lacrosse match. In the evening promenade concert at Sohmer Park, through the courtesy of Messrs. Lavigne and Lajoie.

Saturday, September 12th—7 A. M., excursion to Ottawa at reduced rates.

C. H. Barney of New York has been appointed general manager of the exhibition to be held in Montreal September 7th to 16th, inclusive, in connection with the National Electric Light convention Mr. Barney is now in Montreal arranging for the display. Nearly all of the space has been apportioned, but a few desirable locations are still left.

The Windsor hotel has been selected as the headquarters of the delegates, and the meetings of the association will be held in the spacious assembly room of the hotel. Rates for room and board at the Windsor will be from $3 50 to $5 per day; at St. Lawrence hall, from $2.50 to $4 per day. A rate of a fare and one-third, on the certificate plan, has been obtained on all railroads. Special rates of freight have been granted by the Canadian railway companies, by which exhibitors will be required to pay for one way only, provided the goods remain the property of the original owner.

A yachting trip up the Richelieu river, from Iberville to the Isle Aux Noix, has been arranged for the ladies.

The Frisbie Electric Elevator.

[illegible] on the machine which enables the car to be run at full speed and yet be stopped automatically at the end of the run. A slack cable stop, in the event of the car meeting any obstruction in its descent, engages a clutch on the end of the drum shaft, stopping the machine instantly and locking it so that the car can make no further descent.

In the event of the current being cut off for any reason while the car is descending with a [illegible] governor on the machine, operated by reason of the centrifugal force, throws out a friction clutch and puts on a powerful brake which stops the machine instantly. The motor embodied in the Frisbie electric mechanism is one of the C. & C. Electric Motor company's make, and is fitted with self-oiling bearings and carbon brushes. These machines can be run at a high rate of speed and yet the car can be started and stopped very smoothly.

The D. Frisbie Company of New Haven, Conn., [illegible] New York city is the manufacturer.

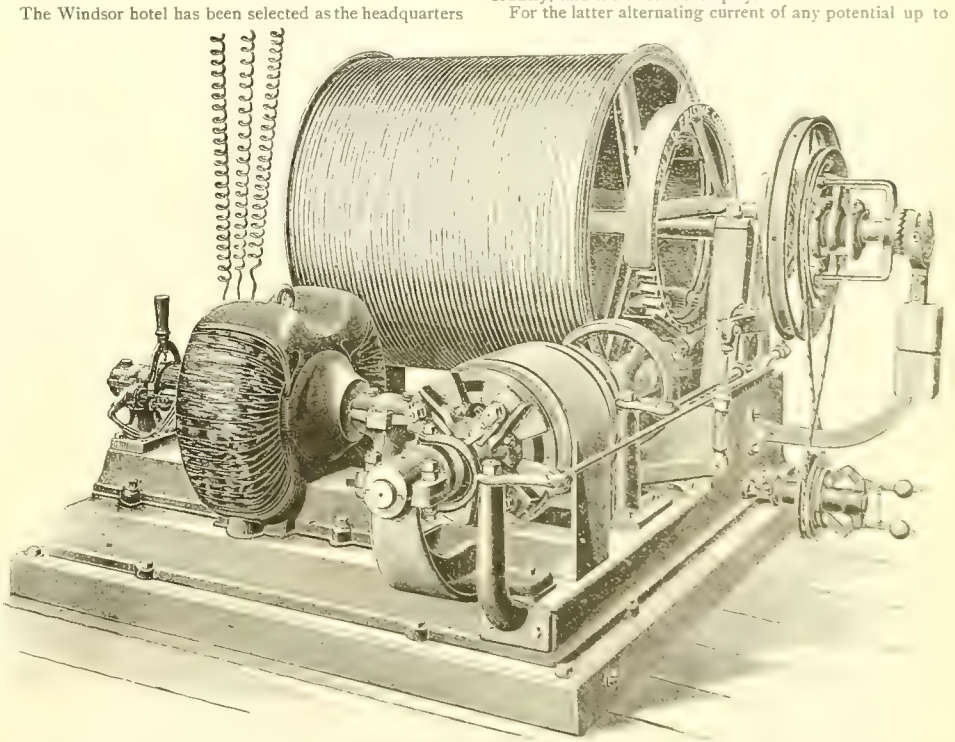
Electricity at the Sioux City Corn Palace.

The electrical display and electric lighting were among the main attractions in the Corn Palace at Sioux City last year, and both will be on a more extensive scale this year, it is promised.

The building will be 380 feet long and 200 feet high, with daylight entirely shut out. About 3,000 incandescents and 50 arcs will be used for lighting and decorating.

The two leading attractions this year will be a South American exhibit, in charge of representatives of each country, and the electrical display.

For the latter alternating current of any potential up to 1,000 volts, direct constant potential up to [illegible] volts and eight amperes can be obtained.



THE FRISBIE ELECTRIC ELEVATOR.

Last year the model electric [illegible] was played, except the ten horse power [illegible] This year desirable exhibits from [illegible] be displayed, and unless sold [illegible] Sioux City Electrical Supply company, which has charge of all the electrical work. The [illegible] festival continues for seventeen days.

The Edison General Electric company has [illegible] an isolated plant having a capacity [illegible] First Minneapolis Hospital for the Insane, [illegible] St. Peter, Minn.

Arc Lamp Hanger.

The cuts represent the action of the Paddock safety arc [illegible] upon the market by the Central Electric company of Chicago. This hanger is simple in construction. It prevents the falling of lamps and all attendant dangers and expenses by reason of insecure fastening, or the breaking of ropes. Combined with the hanger is a sleet proof pulley.

Convention of the Association of Edison Illuminating Companies, New York City.

[illegible] the metropolis at a point where one fears to glance at the scale and the humidity immeasurable, except perhaps by comparison with vapor off the lakes in that region only referred to by those profanely inclined. the Edison people began their midsummer convention in New York at the Murray Hill hotel last Tuesday.

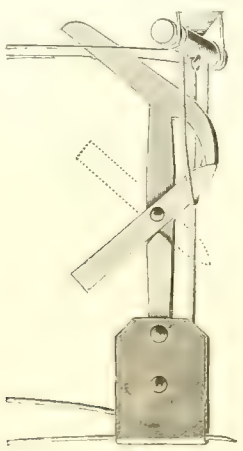
Like the Edison convention, held heretofore, this meeting was conducted behind closed doors. This convention is the seventh thus far held by the association. Tuesday, August 11th, was the day appointed by the executive committee for the opening of the convention, and 10 A. M. found a goodly number of the members assembled for the work of the first session. Among those present the first day were the following named prominent Edison men:

Edison General Electric company, J. Hobart Herrick, vice-president; E. H. Johnson, director, and L. Stieringer.

Lamp manufacturing department, Wilson S. Howell, inspector; Francis E. Jackson, inspector.

Light, power and intelligence departments, H. Ward Leonard, general manager

Legal department, W. J. Jenks, E. W. Hammer, W. H. Lauman.



ARC LAMP HANGER.

Eastern district department, Chas. D. Shain, district manager.

Southern district department, A. H. Reece, district manager.

Official stenographer, W. J. Sullivan.

Edison laboratory, A. E. Kennelly.

Engineering department: G. D W. Williamson, A. E. Winchester, J. H. Vail, assistant engineer-in-chief; W. S. Andrews, technical assistant.

Samuel Insull, second vice-president; J. P. Ord, comptroller; S Dana Greene, assistant to second vice-president; Morris Slattery, agent southern district; F. R. Upton, general manager lamp manufacturing department; Sidney [illegible] manager New England district; W. S. [illegible] engineering department, W. T. M. Mottram, assistant to district manager south district; S. A. [illegible]

Edison Electric Illuminating company, Philadelphia, [illegible] and general man-

[illegible] Paterson, N. J.,

[illegible]

[illegible]

[illegible]

[illegible]

Edison Electric Illuminating company of Brooklyn, N. Y., C. E. Chinnock, director; W. D. Barstow, general superintendent.

Edison Electric Illuminating company of Boston, Mass., Walter C. Baylies, vice-president; C. L. Edgar, general manager; W. A. Hill, cashier; Chas. E. Pattison.

Harrisburg Electric Light company, Harrisburg, Pa., John I. Beggs, director; W. R. Fitzpatrick, superintendent and electrician.

Edison Electric Illuminating company of Detroit, Mich., C. P. Gilbert, secretary and manager; Hoyt Post, attorney; Barton L Peck, motor inspector.

Grand Rapids Edison Light & Fuel Gas company, Grand Rapids, Mich., A. F Walker, superintendent; T. C. Harnish, constructor.

Appleton Edison Light company, Appleton, Wis, A. L. Smith, president

Consolidated Electric Light company, Birmingham, Ala., Leigh Carroll, secretary and general manager.

Des Moines Edison Light company, Des Moines, Ia., J. A. Colby, director, secretary and manager.

Columbus Edison Electric Light company, Columbus, O., A. W. Field, secretary and manager.

Edison Electric Light & Power company, St. Paul, Minn., Geo. H. Finn, secretary and treasurer.

Edison Electric Illuminating company, Lawrence, Mass., W. H. Wolvekamp, electrician.

Edison Electric Illuminating company, Topeka, Kan., W. W. King, superintendent.

Edison Electric Illuminating company, Westchester, Pa., Maurice Hoopes, superintendent

Edison Electric Light & Power company, Kansas City, Mo., W. Preston Hix, director.

Tiffin Edison Electric Illuminating company, Tiffin, O., A. Kaup, manager.

Edison Electric Light & Power company, Little Rock, Ark., G H Van Etten, president.

Elgin City Railway company, Elgin, Ill., C. Wustenfeld, manager.

Scranton Illuminating Heat & Power company, Scranton, Pa, J. E. Parrish, superintendent.

Wilmington City Electric company, Wilmington, Del., C. Regi ald Van Trump, general superintendent and manager.

Toronto Incandescent Electric Light company, Toronto Canada, Frederick Nicholls, manager and secretary.

Renovo Electric Light, Heat & Power company, Renovo Pa, J. H. Sheddy, general manager.

Forest City Electric Light & Power company, Rockford, Ill, M. A Beal, secretary, treasurer and manager.

Mt. Holly Electric Light & Power company, Mt. Holly, N J., J. L. Jamison, superintendent and treasurer.

Edison Electric Illuminating company, Rochester, N. Y., H. L. Brewster, secretary.

Edison Electric Illuminating company, Amsterdam, N. Y., J. H. McClement, vice-president; H. K. McCoy, general manager; T. D. Mosscrop, secretary and treasurer.

Winston-Salem Railway & Electric company, Salem, N. C., J. H. McClement, president; H. S. Cooper, general manager.

Edison Electric Illuminating company, Hazelton, Pa., J. Edwin Giles, manager.

Edison Electric Illuminating company, New Orleans, La., Wm. Oswald, director.

A perusal of the above list of members shows that there were present representatives from a large number of Edison illuminating companies from all over the country, in addition to those sent by the Edison General Electric company and also by Mr. Edison.

The business of the morning was begun with the examination of the delegates' credentials. The convention proper was then formally opened with an address by the president of the association, John I. Beggs of Chicago. Mr. Beggs was followed by A. E. Kennelly of the Edison laboratory, who read the reports of committees on "Grounding the Neutral Wire on Three Wire Systems," and on "Lightning Protection."

A report on "Dangers to Edison Circuits from Crosses with High Potential Conductors," prepared by C. P. Gilbert of Detroit, Mich., was next read by H. Ward Leonard.

A free discussion of these topics followed, in which the convention extended the privileges of a portion of its session to A S. Hibbard, general superintendent of the American Telephone & Telegraph company, and John J. Carty, electrician of the Metropolitan Telephone & Telegraph company.

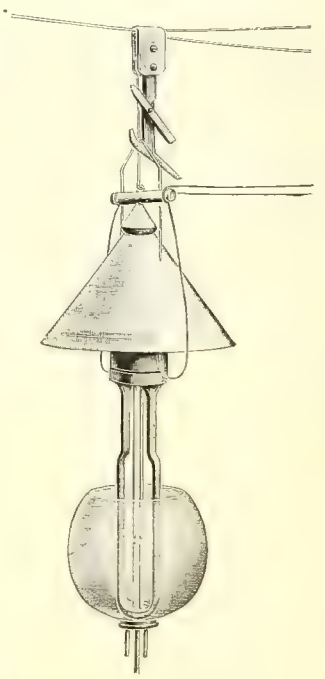
On the reassembling of the members for the afternoon session at 2:30 P. M., the delegates received an invitation from the New York Edison Illuminating company to visit its various stations now in operation, and also the new Elm street station which is in process of construction.

The next feature of the programme was another instance of the New Yorkers' hospitality, for sunset found the delegates seated at the open air tables at the Brighton Beach hotel forgetful of volts and amperes and still under the care of the New York Edison Illuminating company.

[illegible] meeting of the association was called to order promptly at 10 A. M. by President John I. Beggs. The morning was occupied in the discussion of A. E. Kennelly's report on the "Grounding of the Neutral Wire in Three Wire Systems," which was read the day before. [illegible] on of Mr. Kennelly's topic was followed by a [illegible] Prof. Wm. D. Marks, superintending engineer and general manager of the Edison Electric Light company [illegible]. The title of Prof. Marks' paper was, "How to Get Paying Loads for Stations." Next came a paper by R. S. White, on "The Edison Meter in the Brooklyn Station." The morning session was concluded with an address by Samuel Insull, second vice-president of the Edison General Electric company, on the present business policy of the parent company, the outlook in the patent suits the condition of the business, etc. After the close of the business session, the preliminaries of Mr. Insull's trip for Thursday to Schenectady were completed, and invitations for the excursion were distributed.

At the afternoon session of the second day the following named gentlemen read papers: Leigh Carroll, Birmingham, Ala., on "Some Practical Ideas on Distribution;" A. E. Kennelly, of the Edison laboratory at Orange, N. J., on the "Mechanical Meter." Mr. Kennelly exhibited a model and used it for the illustration of points brought out in the lecture. Wilson S Howell addressed the convention relative to 'Peculiar Features of Edison Feeder Systems" Mr. Howell was followed by W. J Jenks on the "Success of the Mutual Insurance Idea in Electric Lighting and Power Stations."

The next thing in order was the election of officers for the year of 1891–92. The following named gentlemen were elected: John I. Beggs, president; C. L. Edgar, vice-president; W. J. Jenks, secretary; W. S. Howell, treasurer. It will be noticed that these members are the same as those which held office the preceding year.



ARC LAMP HANGER.

The executive committee for 1891–92 is as follows: A. L. Smith, C. P. Gilbert, Thos. P. Merritt, H. J. Smith, Leigh Carroll, John I. Beggs (ex officio).

After the election came the report of the executive committee, and the business was continued by the presentation of the treasurer's report.

An invitation was then extended to the delegates by the Edison Electric Illuminating company of Brooklyn to visit its station in Brooklyn at the close of the afternoon session.

L. Stieringer's was the last paper. His subject was "Incandescent Lamps for Decorative Purposes."

The meeting place for '92 was decided in favor of Toronto, Canada, at the invitation of Frederic Nicholls of the Edison Electric Illuminating company of Toronto. This was virtually the close of the convention, for Thursday and Friday were spent in making tours of inspection.

On Thursday the delegates left business behind and 6 A. M. found them on board the train bound for Schenectady and Mr. Insull's "awfully good time." Breakfast was served, according to programme, between New York and Albany. Schenectady was reached at 10:10 A. M., and the delegates scattered throughout the immense factories to see what there was to be seen. Lunch was served on board the cars at noon, and 7:15 P. M. found the convention once more in New York, dinner having been served like lunch in the handsome dining car provided by Mr. Insull.

The New York Illuminating company took the members in hand for the evening, and Madison Square Garden was inspected in more ways than one.

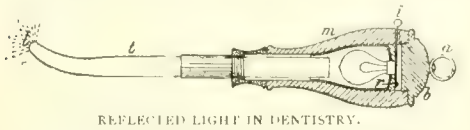
Friday was winding-up day, so to speak; a number of

the out-of-town Edison men availed themselves of this opportunity to visit the lamp works, the Edison laboratory and also the New York Edison works.

Taken all in all and judging more particularly from the list of prominent men in attendance, the last convention of Edison interests was an affair most creditable to those in whose hands had been placed the arduous task of bringing to a successful termination a midsummer gathering.

Reflected Light in Dentistry.

An American dentist in Paris named Michaels has invented a simple device for throwing the rays of an electric lamp into the mouth in order to facilitate dental examinations and operations The idea of the apparatus, which is illustrated in the accompanying cut, is to concentrate



REFLECTED LIGHT IN DENTISTRY.

the light on the spot which it is desired to examine without the annoyance of the heat and bulk of the lamp. This is accomplished by the employment of a reflector and a slightly curved glass tube, to the end of which the rays of light are directed.

As will be seen by a glance at the cut, the details of the device are very simple. The lamp is encased in a wooden holder *m*, fashioned to be conveniently held in the hand of the operator. This handle is closed by a screw plug *b*, to which is attached a ring *a* for the purpose of hanging up the instrument when not in use. The thumb switch *i* serves to control the current, which is fed to contact points by a flexible conductor, not shown in the cut. The light is concentrated into the end of the tube *t*, projecting from the holder, by the polished metal reflector *r*. Only the end *l* of this tube is of clear glass, the rest being ground or colored. It is said that this light has been successfully applied in dentistry, while its availability in other surgical operations is obvious. The cut is reproduced from *Electricite*.

Electricity at the Firemen's Convention.

In connection with the national convention of fire engineers held in Springfield, Mass., last week, an extensive electrical exhibition was made by the Thomson-Houston company. The object of the display was to instruct the firemen in the rudiments of electrical transmission in order that they might more intelligently prevent or subdue fires from wires carrying currents of electricity. The programme, which was prepared by William Brophy of Boston, was as follows:

Fifty arc lamps were placed in the circuit in the building, no outside connection being made.

These lamps were controlled by the ordinary cut-out switch which is usually placed at the entrance of every building.

The method of using the same was explained.

The current was sent through the magnets of an ordinary telephone call-bell, which was protected by the proper fuse.

The current from a fifty light arc dynamo was sent through the same to show the effect.

The current necessary for one or more arc lamps was derived through a short circuit of wire, showing the effect of such current on the human body.

The operation of the arc lamp was explained.

The effects of poor connections in the arc light circuit were shown, and the heating effects that will result therefrom.

The best methods of preventing accidents to persons and property were illustrated.

The difference between series and multiple arc circuits was explained.

Experiments were made to show that current from fifty to 200 volts is not dangerous to persons.

Heating effects of current were explained.

Safety devices and their operations were shown.

The effects of poor work as applied to electric light installations and the dangers of poor insulation were described.

Operations of transformers were illustrated.

Difference between primary and secondary circuits was explained.

Wires from a fifty light arc dynamo, a 750-light incandescent machine and a railway generator were carried into the hall.

Prof J. P. Barrett, chief of the department of electricty, World's Fair, and city electrician of Chicago, was in attendance at the convention.

On Wednesday evening Mr. Brophy made some electrical experiments and delivered a brief address on the subject of handling electric wires. He was assisted by H. S. Anderson, superintendent of the United States station in Springfield. Mr. Brophy said that the danger of such wires causing fires was principally from defective insulation. Several illustrations of poor work of this kind were given. In closing Mr. Brophy said that by proper appliances the dangers of electricity could be reduced to a minimum. He thought that those who furnish bad work should be held criminally responsible.

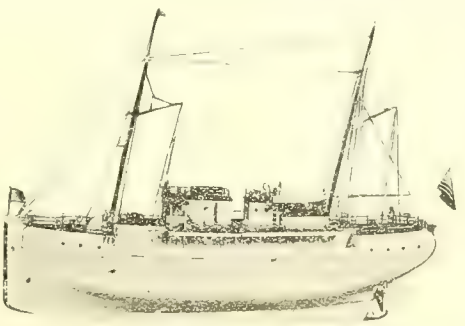
Among the exhibitors at the display of apparatus were the Gamewell Fire Alarm company, New York; Gamewell Auxiliary Fire Alarm company, Boston, and Shaffer's Automatic Sprinkler & Fire Alarm company, Milwaukee, Wis.

Gregory's Electrically Driven Model of an Ocean Steamer.

There are, perhaps, few electrical engineers already in possession of spurs well won who cannot remember their first attempts as amateurs to build electrical apparatus. How many can look back to the time when they lay awake nights plotting and planning some little device with which to astonish "the other boys," the majority of whom had neither the inclination nor, oftentimes, the brains to investigate even the simplest electrical effect? It might be ventured, too, that there are not a few who might resurrect, from that safe hiding place among the rubbish of the garret or store room, "my first dynamo, built with my own hands!"

The outcome of the first real practical effort is the treasure; so among those who read of the little ship Miramar, there will in all probability be some who will feel a genuine pleasure in extending, as does the WESTERN ELECTRICIAN, words of encouragement to Julian Gregory, the builder

Several months ago young Gregory, who, by the way, is but seventeen years of age, told his father that he believed he could construct an electric motor of sufficient power to propel a small pleasure launch. His idea was to supply the current from primary batteries. The elder Mr. Gregory was somewhat skeptical, but not wishing to discourage his son he suggested that the better plan would be first to construct a model. If the experiment were a success, the



GREGORY'S ELECTRICALLY DRIVEN MODEL OF AN OCEAN STEAMER.

young electrician was to receive more substantial encouragement to aid him in equipping a larger craft.

Young Gregory went to work with a will, and the accompanying cuts will give the reader some idea of what he accomplished. It is to be understood that the model as an entirety was constructed by young Gregory.

His letter descriptive of the work and also the line drawing of the vessel are given as they were received. Master Gregory writes:

"My electrical ship Miramar is 36¾ inches from stem to stern, and 8½ inch beam.

"It is a perfect model of an ocean steamer fitted on the inside with saloons and motor room, and lighted by electricity. Each light has a separate battery with the exception of one in the motor room, which is lighted by the large main battery.

"The motor is run by six cells of bichromate battery, which are all inclosed in an acid-proof compartment, with the exception of one in the motor room. The propeller makes 240 revolutions per minute in water."

Several days ago the model was tried on Oak's mill pond at Glen Ridge, N. J., which is the builder's home. It was a success; and it is almost needless to say that Julian Gregory is now in a position, as far as his father is concerned, to experiment with a larger motor and boat.

An Enterprising Superintendent.

To say that electrical men are never without resources would only be giving credit where credit is due. But there is an electric light superintendent in Pittsfield, Mass., who deserves a great big city station. One day last week Manager Gardner of the Pittsfield electric light company, was notified that the water was to be shut off at six o'clock to repair a break in the main. As most people are aware an electric light plant cannot be run without water, and how to get it in sufficient quantities was the question. Four large street sprinklers were filled with water and taken to a position near the boiler. Several teams with a lot of extra men were started out and returned with 153 water-tight

[illegible]

thing in it."

Telegraphers in Convention.

[illegible]

question of securing recognition of the members of the military corps by Congress. The address of the president, W. R. Plum, herewith presented, was devoted almost exclusively to this topic, and will prove generally interesting.

Having held our reunions in Niagara Falls, Chicago, St. Louis, New York, Cleveland, Pittsburgh, Detroit and Kansas City, we now meet at the great civic and military headquarters of the nation, in many respects the most beautiful city on the continent.

From this standpoint it behooves us to take a cursory view of the rise and dismissal of our corps, whose splendid example in war occasioned all the governments of civilization to engraft a like service as a part of their army systems.

When, on April 12 1861, the cannon in Charleston harbor cemented the confederacy and unwittingly sealed the death warrant of disunion and the only potent object for it, the telegraph resounded the echo northward beyond the great lakes and westward beyond the plains

In three days after the call for 75,000 Union troops fully 100,000 were preparing to respond.

Boston Commons contained troops from various parts of the state the night of the first day, and Pennsylvania forces reached this city at 7:30 P.M. April 17th, Baltimore was in the hands of a secession mob. Harper's Ferry was captured the 19th. The same day the Richmond wires were cut, thus severing all southern connection except via Kentucky, whose lines were intact until September. April 21st, Philadelphia was cut off, and the nation's capital became the object of intense solicitude

The enemy having destroyed portions of the railroad and telegraph between Washington and Baltimore, Thomas A. Scott called to his aid Andrew Carnegie first, and shortly after David Strouse, D. H. Bates, Samuel M. Brown and Richard O'Brien, all from the Pennsylvania railway, for the purpose of operating the railroad from Baltimore to Washington.

These telegraph experts were the first in the Federal service, and unwittingly, by mere development, formed the necleus, in this vicinity, of the army telegraph corps which, during the war, constructed 15,389 miles of military telegraphs and sent 6 500,000 telegrams.

The first military line ever constructed on the American continent was built in April, 1861, connecting the War Department with the navy yard, and though new lines were constantly being built hereabouts, yet, for the first seven months of the war, the American Telegraph company, under the presidency of E. S. Sanford, advanced nearly every dollar expended in their construction and operation in eastern Virginia, Maryland and the District. The other necleuses were organizing about Wheeling and St. Louis also, without warrant of law.

Nor is this surprising, for, except perhaps an untried corps in Germany, no army system in the world embraced a telegraphic department. Even our signal service employed but one man, who did not reach Washington from the Indian country, until June.

Thus was the great civil war inaugurated, and McDowell moved to defeat at Bull Run, leaving his nearest telegraph offices at Fairfax Courthouse and Burks Station. At the same time General Patterson was near Winchester with no telegraph nearer than Harper's Ferry

Had Generals Scott, McDowell and Patterson been in constant telegraphic [illegible]

GREGORY'S ELECTRICALLY DRIVEN MODEL OF AN OCEAN STEAMER.

the battle of Bull Run would not have occurred in the absence of Patterson's forces.

This first great disaster of the war [illegible] demonstrated the necessity of constant telegraphic access to advancing armies, and was in sharp contrast with the example previously set in western Virginia, where McClellan was in constant telegraphic [illegible] moved to victory at Rich Mountain.

In Missouri General Lyons' army was defeated by superior forces at Wilson's Creek, [illegible] twenty five miles from the nearest telegraph [illegible] courier after courier was dispatched [illegible] succor, although troops were at hand to relieve far less exposed points in the department.

When General Fremont took command of this depart-

...gested that his plan was to organize a telegraph ... companies were partially organized, armed and drilled for this special service, under the plan of Major George H. Smith, the commander, contemplating ... in any emergency, so that time and expense may be saved, each operator to be furnished with a pocket instrument, to open communication from the field of battle or the marching army to headquarters, or elsewhere instantly;" but under the civic plan of Anson Stager, who in the meantime had been appointed superintendent of all United States military telegraphs, with the rank of captain, by order of the secretary of war, the battalion was disbanded after having constructed several hundred miles of line.

Henceforth the telegraph became an indispensable adjunct to each of our armies and every post, and in its fuller development, also, of every army corps, and frequently of lesser bodies.

The operators accompanied the troops in every campaign and numbered, all told during the war, about twelve hundred. They were sworn into the service, taking an oath substantially as follows:

"I do solemnly swear that I will bear true allegiance to the United States of America, and that I will support and sustain the constitution and laws made in pursuance thereof, as the supreme law of the land anything in any state constitution or laws to the contrary notwithstanding. That I will not take up arms against the United States, or give aid and comfort to the enemies thereof, or to any authority or pretended authority that is or may hereafter be engaged in armed hostility thereto; and that I disclaim all fellowship with the so called Confederate states and Confederate armies. I do further swear that I will not reveal to any person or persons the contents of any dispatch, report or other communication, either directly or indirectly, that may come to my knowledge through my connection with the telegraph, in any manner whatever. That I will not reveal or divulge to any person or persons any cipher that may be given me for United States military purposes; and that I will faithfully keep and observe this my solemn oath of secrecy and allegiance to the government of the United States of America."

The telegraphers in the various departments were under the military orders of the commissioned officers, who were given rank in the army solely in view of such a command. Not one of them ever had any other duties assigned to them These officers were Captains Bruch, Smith, Bulkley, David, Whitney, VanDuzer, Fuller, Gross, Gilmore, Clowry and Lynch, Major Eckert and Colonel Stager.

Bruch died of disease at Memphis; Smith, David and Bulkley resigned and were mustered out; the others, at the close of the war, were "honorably mustered out of the service in the armies of the United States" with a brevet lieutenant colonelcy except Stager and Eckert, who were brevetted brigadier generals, while the operators who had borne the brunt of the service were simply told to quit and go home. No discharge was granted them; not even a commendatory order was ever issued by our own chief; and now, at this late day, when over half of our comrades are in their graves, although for eight years we have sought congressional recognition, yet six favorable reports upon our bill from Senate and House Committee on Military Affairs declaring that we were an integral part of the army, and should be recognized as such, is as far as we have progressed in Congress.

The House Committee of the last Congress, however, in its exceptional (?) wisdom, presented a substituted bill which declared that the act should not be construed as ... as a part of the army.

The reasons the committee reported why the bill should pass clearly justify the former findings of the other military committees

Among other things this committee reported were:

"The men of such service were of unusual intelligence and showed themselves possessed of a courageous spirit and indomitable pluck. No men who served with the army showed themselves possessed of these traits to a greater degree. They put up their instruments many times on the skirmish line and frequently almost by the lines of battle. They went with the advance and were often the last to leave an abandoned position even when it meant capture and imprisonment. Some were killed at their posts of duty, many were wounded and crippled for life. . . . They were made prisoners of war and exchanged for important officers. They were to a certain extent subject to military orders, but have never been able to claim a ... among the nation's defenders. Some held an assimilated rank, but ... were just as in ... though they had ...

This committee supplemented its report with communica ... Their duties constantly placed them in exposed positions, and they are favorable objects of rebel surprise. It is much to be desired that some mode of recognizing and rewarding the bold, faithful and most important services of these gentlemen should be provided."

The Committee's Exhibit of the Reports of the Committees of the 48th, 49th and 50th Congresses show the following statements, approved by it: "The reports of the secretary of war and the commanding generals bear uniform testimony to their efficiency, intelligence and patriotism. Their duties were purely military and were performed with the same exposure to the dangers of the field and disease as fell to the lot of the ordinary officer and soldier. . . . By the efforts of personal friends, their history has been collected, and it is known that of the entire number 199 were either killed, died of disease or were captured while in the line of duty. It is estimated that more than 100 others suffered from the casualties of the service."

It was "organized . . . upon a quasi military basis; . . . its operators were sworn into service"

"The services performed . . . were of such importance and efficiency that every European nation and our own government have since reorganized their army systems so as to include an electric telegraph corps to perform the same telegraph duties that were required of the United States Military Telegraph Corps in question. In addition to their strictly military telegraph service, the operators were . . . the custodians of all cipher keys, and required to put into cipher and translate all important dispatches, and thus they became, and continued throughout the war, most confidential and trusted aides engaged in the courier service, transmitting about 6,000,000 dispatches" Their 1,000 miles of field wires "were ofttimes worked on the field of battle and under a heavy fire." Then follows the commendations of some of the most prominent officers of the army.

This bill was put upon its passage without (by reason of unforeseen events) the knowledge of our committee on congressional action, notwithstanding our society at Kansas City had repudiated it, and so advised the House Committee.

Thereupon I proceeded to this city, and being ably seconded by Comrade Stafford, we had no difficulty in securing an adverse report on this bill, and a favorable one on our own from the Senate Committee, but, by an oversight, consequent upon the pressure of an expiring Congress, the House bill was presented with the report instead of the one actually approved by the Senate Committee.

Owing to this mistake, and the few remaining days of Congress, it was evident that nothing could be accomplished except the prevention of the passage of the House bill, which Senator Hawley, for whose many kind offices we should ever feel deeply grateful, assured us of. Such is the present situation.

We have established the facts that we were sworn into the service; that we were exposed to the dangers incident to the army in war, that our service was the counterpart of that of the Signal Corps, which was honorably discharged and which lost far less in the casualties of war than we; that we alone of all the army were intrusted with the cipher keys; that we wore officers' uniforms by general orders, that 175 enlisted telegraphers were permanently detailed or discharged from their regiments to enter our service; that the war department discouraged the enlistment of telegraphers in other branches of the service and by general order prohibited their conscription; that we unavailingly petitioned our chief during the service to organize us distinctly upon a military basis that our officers alone of our corps were entered upon the army rolls; that we were solely subject to military orders; that we operated our wires upon the field of battle in every territorial departement; that every important cavalry movement was accompanied by one or more army telegraphers; that in the great movements, especially from the fall of 1863, every section of the armies in near proximity to the enemy was kept, even on the march, in constant intercommunication; that unparalleled facilities for communicating with distant forces were provided by us; that thousands of lives and millions of treasure were saved by the timely aid of the corps; that the war was shortened, perhaps years, by concentrative and co operative use of the telegraph, which first declared victory or defeat, the need of troops, of munitions of war, of quartermaster, commissary and medical supplies; which patroled the sea coast and the whole army front, keeping every post and division in constant touch and, in emergencies beat the "long roll," to arms. We have shown that the history of the war was thus preserved on paper largely in the handwriting of the actors themselves; that its history is the most authentic up to that time in the annals of war; that our people in the North were encouraged, stimulated and assured by hourly reports, thus minifying to the least degree the sad worriment that war brings to the lonely hearthstones where parents, wives, children and others prayed and rejoiced or wept

Ours was the mystic chord which alone enabled Grant to command a million of men and brought assurance and repose to many a commander during all hours of the day and night, for its operatives kept vigils night and day in the fort, in the tent, in the lonely bivouac, on the ground, in the malaria of the Chickahominies, or the Yazoos, in unprotected guerrilla countries, and upon the battle fields; ... in peril of danger, but as secretive of confidential ... are the bolts and bars of the federal treasury.

We have seen our comrades shot down in battle, torn to ... by ... torpedoes, imprisoned in Libby, Anderson... ... and other hostiles, where many died and ... helpless wrecks. We have seen them in ... of ... and other fever, seen them at ... and emaciated by chronic diarrhea or other camp diseases until the hospital or the grave wrought ... We ... them in later years in the county ... because there was no pension for them, save what we donated, and we now know that ... are in their graves unthanked and unhonored.

We propose to go there also undamned by invidious praise, rather than accept a certificate of creditable service as camp followers.

The narrowness of the last House Committee's bill is the more remarkable when we consider that the Grand Army of the Republic representing 410,686 survivors of the army and who ought to know, had already solemnly resolved that we were a part of the army and as such should be recognized.

This was supplemented by the resolution of the society of the Army of the Tennessee, and that of the Ohio legislature

There is no question of congressional power; it is purely one of legal recognition of an actual status. Nor is there any moneyed idea, for it is simply one of sentiment; of being placed in peace alongside of those who in war were and in peace are glad to welcome us.

We solicit no pension, nor bounty, nor further compensation. Ours is not a raid upon the federal treasury, but an insistence upon a *de jure* recognition of a *de facto* status.

In the light of our services, exposures, deaths, wounds, capture and imprisonments, sufferings and deprivations, all voluntarily risked, solely from patriotic impulse, this governmental silence for twenty-six years touching the value and dangers of the corps, while justly heaping unparalleled thanksgiving and thankofferings upon our comrades on the adjutant's rolls, is a striking illustration of the ingratitude of republics as represented in congresses, where thanks originate so largely through fear of an individual loss or hope of gain of constituent votes. Scattered all over this land of 60,000,000, we have have no power but the influence of a just cause, reinforced by the testimony of nearly half a million surviving veterans, their great generals and the reports of six millitary committees, themselves, perhaps, wholly composed of ex-officers of the war.

Death is reaping a rare harvest of our gallant witnesses. During the last year it removed [General Sherman, who wrote that "the greater number were distributed along the lines, had to work day and night, and were as much a part of the army as though armed with muskets in the ranks; for before the discovery of the magnetic telegraph, the sending of messages back and forth, to and fro, was always done by armed cavalry messengers and escorts, consuming a large portion of the active army. In fact there should have been in the civil war a regular corps of telegraph operators with regular muster rolls, so that the wounded and disabled could be entitled to the same pension as other staff soldiers and officers."

It behooves us to take action upon his demise, as one of our stanchest friends and greatest commanders. Among other witnesses called hence we may note General Grant, who declared that "the telegraph and the signal service, its coordinate, were as necessary to our success as the railroad is to commerce. Nothing could be more complete than this body of brave and intelligent men. The operators were assigned to particular headquartes and never changed except by special orders The moment the troops were put in position to go into camp, all the men connected with this branch of the service would proceed to put up their wires . . . Thus, in a few minutes longer than it took a mule to walk the length of its coil, telegraphic communication would be effected between all headquarters of the army. No orders ever had to be given to establish the telegraph." Also General Sheridan, whose testimony was that "in my own experience I found them (military telegraphers) invariably active, brave and honorable." Also General Logan who championed our cause in the Senate, and who said: "No part of the army during the war discharged its duties more diligently and faithfully than the telegraph corps."

Also, General McClellan, who testified: "I do not not think that any one appreciates more highly than I do the value of those services and the loyal and invaluable devotion so constantly displayed by the men. I had ample occasion to recognize the devotion to duty which so often kept them at their posts in the midst of danger; the patience, intelligence and thorough honesty they displayed, and the great debt—still unpaid (1883) and too little recognized—due them by the country. I sincerely trust that they may receive the recognition they so richly merit, and cannot doubt that upon a presentation of the case, Congress will take favorable action."

Also General Burnside, whose evidence: "I have no hesitation in saying that the telegraph corps was of infinite service during the late war, and I am free to say that I never knew a body of men who possessed more integrity, industry and efficiency than the operators with whom I was thrown."

Also, General Warren who wrote of an operator bringing his line and operating his instrument within musket-range of the enemy under a heavy cannonade, and again, of another under a severe musketry fire, and added: "I don't want to see the telegraph operator in the war neglected, as far as I can have anything to say."

Also, General Franklin, who recalled that it was always a pleasant surprise to him within an hour or two after a long day's march that the wires were brought to his quarters, thus saving the lives and time of couriers and horses, and giving a comfortable feeling of security which would otherwise have been wanting; adding that "The duties . . . were so well performed and the men themselves so modest and unobtrusive that their merits have not received sufficient notice from the generals with whom they served. I know of no class of men in the army who were more faithful and energetic. . . . I always found them alert, intelligent and courageous."

Also, Secretary Stanton, who officially reported that: "The military telegraph has been of inestimable value to the service, and no corps has surpassed, few have equaled, the telegraph operators in diligence and devotion to their duties."

General J. M. Schofield, at present in command of the army of the United States, wrote the chairman of the Senate Military Committee that "there is no question, in my judgment, that the persons engaged in the military

telegraph service during the late war deserve recognition for the bravery, fidelity and skill with which they discharged their duties, and that they should at least receive a certificate of recognition and honorable discharge from the service. . . . There would, I think, be no objection to naming the assimilated rank in the certificate of discharge if it could be fairly ascertained. But, in view of the difficulty which must be encountered in any attempt to do this at this late day, it would probably be better for the members of the military telegraph department to be content with a certificate of honorable discharge, in which should be mentioned the grade of the service in which each was employed. The war department could readily prepare a form of certificate which would contain all that can reasonably be desired, without attempting to determine relative rank."

If to this convincing evidence we add that of Generals Rosecrans, Banks, Sanborn, Haupt, Compte de Paris, G. A R. Commanders Warren and Veazey, and the declaration of 410,686 other living veterans, that the corps "constituted, in fact, a part of the Union army and partook largely of its hardships and dangers while rendering invaluable aid," and that Congress "should promptly recognize the status and services of the corps," which it has wholly ignored though many "were killed, wounded, or died at their posts of duty," do we not make a case that should shame every congressman who fails to do what he can to secure for us an honorable discharge from the army, and should we be content with anything less?

After waiting long in silence and knocking at the doors of Congress eight years for some sign of appreciation, shall we be put off with a recognition that classes us with the army sutler; that debars entry into the Grand Army of the Republic; that we cannot hand down to our children as proof that we were more than hirelings with the army; that forbids the government from erecting the usual headstone at our grave and refuses our bones an interment among the nation's defenders?

No, a thousand times no. Better to "die like a dull worm, to rot; thrust foully into earth to be forgot," than accept from the representatives of a great people a long deferred and niggardly certificate that entitles us to nothing, and on its face expressly declares that out of nothing nothing shall come. If it was justice to make officers of those in command of us, and honorably discharge them with increased rank, three months' extra pay and transportation home, while we who bore all of the casualities of the service, except in Captain Bruch's case, were dropped from the rolls at our posts of duty unhonored and unthanked, the query arises, Why in time of peace has our own government since established the military telegraph service as a coordinate branch of the army, and why has every civilized government of the globe done the same thing?

Here in the capital of a united and loyal nation let us again resolve, as we did last year at Kansas City, that a discharge from the army is a *sine qua non* to any acceptable certificate.

Frankfort Electrical Exhibition.

By F. B. H. Paine.

The exposition was opened officially on May 16th, and is now nearly completed. The grounds have an area of about 20 acres, in which there are an artificial hill, a pond, etc. The buildings are mostly occupied by the exhibitors of electrical apparatus, but there are also a theater, where a good farce or music may be heard; a cyclorama of the harbor of New York as seen from the deck of one of the great steamers, the entrance being through the cabin, and so capitally done that one can perceive the ship's smell, also numerous beer gardens and two band stands.

Entrance to the grounds is through the old railroad station, in which are the offices, reading room, press bureau, etc., of the exposition. The first building contains a collection of medical electrical apparatus, some fine testing instruments and toys In one end Siemens & Halske of Berlin, and other Siemens manufactories have a collection of their electrical instruments for all purposes, with dynamos, motors and accumulators to put them in operation. In an adjoining building Siemens & Halske have a small model theater with complete arrangements for showing the scenic effects possible to attain with electric lighting.

From here we go around the artificial hill, surmounted by a pretty wine garden, through which flows a stream of water that tumbles over the cliff, making a waterfall of considerable size. Under the cliff is a cavern from which a great dragon is crawling and vomiting hot water and steam; at night the dragon and cavern are beautifully illuminated with changing colored lights.

Under the hill is a "drift," in which Siemens & Halske show their electric mine locomotive and other mining apparatus. The locomotive pulls a passenger car into the "mine," on which everybody rides, to the delight of those who have never been underground. The apparatus is similar in design to that in use in the United States. They use a ground return wire and copper overhead conductor supported in the usual way. The trolley used, however, differs entirely from those in America, but has the same characteristic that makes their street car trolley worthy of notice. They have a line running from the grounds to the opera house, with two cars working on the trolley system and one or two with accumulators. Instead of a wheel or spoon, as used in the United States, they have a steel rod nearly as long as the car is wide, supported in a somewhat similar manner to our trolley wheel. It has many advantages, the principal ones being that it cheapens the line construction greatly, as no switches need be used to guide the trolley, and with it it is unnecessary that the trolley wire should conform to the curve of the track exactly, as contact can be made at any point on the cross-rod. The pole is attached to the car as ours are, except that it is much shorter; the hinge and springs, instead of being on the car roof, are raised considerably above it; the pole, being shorter, stands straighter, and when the direction of the car is changed it flops over, raising the trolley wire just a little

From the "mine" we cross an open space in which is a band stand and enter the main building, at the entrance of which is the electric light exhibit of Schuchert & Co. of Nuremberg showing their direct and alternating current machines, lamps, etc Then we hear the familiar "buzz" of a Thomson-Houston arc machine, and beside it stands one of their street car generators. It seems strange to see these old friends in the hands of people who do not understand the language in which they were built

In the center of the building is the largest dynamo in the exposition an alternator built by the Helios Electric Light company of Cologne, under the patents of Zipernowsky-Deri-Blathy, who are the experts of Ganz & Co. of Buda Pesth. This machine has a capacity of 600 horse power with an electro motive force of 2,000 volts. It is provided with an internal revolving field with 40 laminated pole pieces bolted to a cast iron frame keyed to the shaft, which is directly connected to a compound engine of 600 horse power, one cylinder on each side. The engine makes 125 revolutions, giving the dynamo 2,500 periods per minute (about one-third the periods usually employed in America). The latter is excited by a separate direct current machine, The dynamo is about 10 feet in diameter. The Helios people have adopted an ingenious switching apparatus with levers and interlocking arrangement, by which they are enabled to regulate the current, throw the alternators into multiple-arc, and accomplish all the work usually done by separate switches placed upon a switchboard. It is questionable, however, whether they really simplify the central station or are less liable to accident than with the old way, although they do somewhat lessen the work of changing over, etc.

At the far end of this building is Siemens & Halske's principal installation, consisting of many direct current dynamos of small size; direct current machines coupled to alternators, one acting as a motor and the other as a generator, as the case demands; also two direct current machines on the same shaft, one acting as a motor and the other as a generator, their use being to transform a direct current of high potential and small current into one of low potential and large current, or *vice versa*. This is, of course, done at considerable loss. At one side stands their largest type of direct current dynamos directly connected to an upright triple expansion engine. The dynamo has an internal stationary field of four or six poles, according to the size of the machine, which are bolted to brackets on the foundation. Through a hole in the center of the field the shaft revolves, keyed to which is the cast iron web supporting the external revolving armature, the core being of laminated iron, bolted to the web, forming a Gramme ring. The winding consists of almost innumerable copper hoops, bent so that they exactly fit, insulated from each other and the outside surface turned off smooth, each hoop being one turn and forming one bar of the commutator. Thus the whole exterior of the armature is the commutator, on which press as many stationary brushes as there are poles, supported by a very ingenious brush holder, so arranged that all brushes are moved together over the surface of the commutator by one motion, giving more or less lead, and by another altering the pressure of all brushes or removing them entirely from the commutator.

By the side of this great direct current machine stands a new alternator directly connected to its compound vertical engine. This machine is of about the same size as the other, with an internal revolving field and an external stationary armature wound for a comparatively low electro motive force, for an alternating current. As the machine has as yet never been run, nothing is known as to the efficiency or the advantages to be gained by its form of construction.

In addition to those mentioned, there are a great many dynamos, engines, gas and petroleum motors with no peculiarly novel features, all doing their work and helping to make a wonderfully fine display.

A few common and prominent characteristics mark the difference between the European and American dynamos. In Europe designers favor commutators with a great diameter; a few are using small steel ones, with an air gap for insulation, copper brushes being always used; even for motors the carbon brush is rarely seen. Almost all European dynamos are built with a great clearance between armature and field, they believing that the loss in efficiency is more than compensated for by the better regulation of the dynamo. Americans believe that we make as close a regulating dynamo as they, and at the same time run with as small a clearance as is possible to make. The greatest difference, however, is that in Europe the tendency is toward great cumbersome machines running at a very small number of revolutions, while in America we make a compact machine running at a great number of revolutions, and get as much service from a pound of metal as possible. Which is better? It seems as though the different conditions existing in the two countries demanded different apparatus.

Arc lighting in Europe is superior to ours, due chiefly to the use of much better carbons. There all arc lamps are operated in parallel, as we run incandescent lamps, and from the same machine. This custom demands the use of more copper in mains, but greatly simplifies the central station.

On emerging from this immense building we are greeted by the stars and stripes floating over a little round pavilion bearing a prominent sign, "American Bar;" it does not look entirely American, but they do know what a "whisky sour" is! Close by is the gate leading to the exhibition of electric light projectors for marine use, situated on the river bank, with a lighthouse on which is one of the most powerful projectors ever made. Schuchert & Co. and Siemens & Halske monopolize this section, Siemens & Halske also exhibiting models of their torpedo firing apparatus, etc.

Schuchert & Co. have built a short electric street car line from the main grounds to the Marine Department that system and the underground conduit system, with its

time and they are both covered by the car, the current being

contact strip set into the pavement. The only novel feature is the use of the iron filings, the action of the magnet

it looks as though the use of the filings might so simplify the arrangement that it would be a practical success.

There are two small buildings devoted to a wonderfully beautiful display of electroliers from the works of some of the best European manufacturers. At the end of the grounds the Otis Elevator company has built a tower about 100 feet high, up which one of its electric elevators carries passengers for

tion. On the side of the ground opposite the main building are three long ones, the first containing long distance and loud speaking telephones, Edison phonographs, etc.; also a very extensive exhibition of telegraph instruments of all kinds by most of the European makers. In one part of the next building are shown some systems of railroad interlocking signals and other apparatus for railroad use in which electricity plays a more or less important part. Nothing important, however, is new. In this building two manufacturers show portable electric light plants intended to be drawn by horses; boiler, engine, dynamos, poles, wire and lamps, all well arranged for instant use. On one a Westinghouse standard engine is used, and on the other a Brotherhood, both directly connected to their dynamos.

The Royal Prussian railroad exhibits a car carrying an electric light plant, of larger dimensions than the two just mentioned, for use in case of accidents. In one end across the car is a boiler with firebox on the side. Close to the boiler is a Westinghouse engine belted to a dynamo. The apparatus is admirably arranged with everything necessary ready and in convenient position for instant use. The poles and wires are carried on the roof

The third building is devoted to an interesting exhibition of apparatus for various electrolytic processes, shown in operation, and also some of the products. The Algemeine Electricitats Gesellschaft has a large and interesting collection of the articles made in its Swiss works from pure aluminium and its many alloys, which may be considered in one sense products of electricity.

The proposal to transmit 300 horse power from Lauffen to Frankfort, 110 miles, has made the Frankfort Exposition most notable in America, although the work is not yet under way and can not be completed before September 1st, if so soon The intention is to use a multiphase or rotating current of 30,000 volts. The results of the experiment are awaited by the electrical world with bated breath, and, if successful, will enlarge our present views of what is practicable in electric transmission of power,

It will be impossible to realize the size and interest of this exposition from such short and very general notes as these, but some conception of it may be formed from the fact that the boiler power, with that of the gas and petroleum motors, is 3,800-horse power, much of which is again delivered in additional power by electric motors, making in all about 4,800-horse power in use every night.

The pleasantest time to visit the exposition is about five in the afternoon, and after four hours' hard work we come out of the electrolysis building tired and hungry. At the sight of the Munich beer garden brilliantly lighted, the pretty Bavarian girls in their native peasant costumes, covered with bangles and bright decorations, running in and out among the little tables filled with contented Germans, with now and then one of another nationality, we are immediately conscious of an irresistible thirst; but with a litre of beer before us we soon become as happy as the rest, and finish the evening in listening to a good military band and the latest gossip in German, while watching the crowd.

1. From the *Railroad Gazette*.

CORRESPONDENCE.

New York Notes.

New York, Aug 15.—If the convention of the association of Edison Illuminating companies had not been held behind closed doors, this week's issue of the Western Electrician would be teeming with columns of matter interesting to those identified with constant potential distribution. But it is the policy of the Edison company to maintain a strict privacy on all except the most general matters. Doubtless this course is a wise one, for secrecy, nowadays, seems to be worth any number of patents, in that to maintain your rights there is no need, where secrecy is employed of resorting to the law. There was a full attendance in spite of the intense heat and hard

sphere. As one delegate remarked contemptuously, in reply to a question as to the possibility of an afternoon session "Edison men don't mind a little heat." Whether the mysterious sessions had their own peculiar charm or the thought of Mr. Insull's "awfully good time" kept them patient is difficult to decide. Such sessions as these were too hard for the long suffering newspaper men who waited in the hallway of the hotel for the news that never came.

Another of the periodical exhibitions of the Sims-Edison

torpedo was given this week. It is asserted that in this test all former speeds of government torpedoes were exceeded. It is claimed that under the manipulation of W. Scott Sims, the co-inventor with Edison, the little craft made as high as twenty miles an hour. This rate of speed is two miles more than the contract with the government requires. The trial was made at Willet's Point, and was witnessed by a large number of army and naval men, together with several representatives of foreign governments. Mr. Sims is to go to Europe to superintend the manufacture of his weapon at a factory which has just been established near Havre, France. An invitation has come from Turkey to exhibit the working of the torpedo in that country. Sir William Armstrong of England, also, has placed a vessel at Mr. Sims' disposal, from which to operate the apparatus and exhibit it to the British admiralty.

Again we have an instance of the complacency with which some of the daily newspaper editors undertake to write knowingly on topics just a little beyond them. "Steam gets a new lease of life," says the scientific scribe, who fills space for the New York *Evening Sun*. "Of the thousands of dynamos now in use in civilized countries at least 95 per cent. are driven by steam, the remainder being driven by water power. So that the time when we shall become a steamless world seems almost as far off as it did to the great railway kings of half a century ago."

It is to be presumed that the elderly gentleman—elderly, because a young man would know better—who writes these words of consolation had a dim idea that a dynamo, like the perpetual motion machine, runs itself. Will some people never awaken to a realization that electricity, whatever else it may prove to be, is merely an agent.

Here is another, but not so bad, from the *New York Tribune*. Speaking of Boston's action in regard to burying the lighting wires an editorial paragragher undertakes to "crow" at the expense of the Hub's street railway system. "We are better off in one respect than Boston is in the matter of wires. Boston is afflicted with the intolerable trolley system in an aggravated form."

This man must be a night editor—at any rate he writes in the dark in more ways than one. A careful glance down Broadway would, perhaps, check his enthusiam over the "thoroughness" of Mayor Grant's hasty work.

The storage battery people are already getting to work. Now that the stumbling block of possible litigation has been at least partially removed, we may look for rapid progress. The Newark & South Orange Horse Railroad company, through its president, John Radel, is reported to have entered into negotiations which may lead to the equipment of the line with the storage battery system. A New York company is to be allowed the privilege of demonstrating whether accumulators will do the work required.

It is customary for journalists to inform the reading masses that it is hot when the mercury reaches 90°. Your correspondent, then, merely claims his rights by referring to an "electrically" storm. Storms in summer are, of course, not usually electrical, but, perhaps, Elizabeth, N. J., was favored. Passing over the everyday incidents, such as the striking by lighting of a church spire, the killing of a horse, and the stunning of a boy, it may interest inventors of safety cut-outs for telephone circuits to know that the Elizabeth system as well as that of Perth Amboy and Rahway suffered greatly—120 telephones, in fact, are reported to have been burned out in Elizabeth. The usual fireworks on the switch-boards were the order of the day. Coney Island, it seems, also had its electrical display in the shape of a thunderbolt, which struck the old iron pier.

Now that we are treated almost daily to a description of [illegible] interesting application of electricity, one hesitates to devote much space to an account of the [illegible] but as not every ball room is a Vanderbilt's, and few others could afford so brilliant a [illegible] of interest to [illegible] paragraph taken [illegible] account of Mrs. F. W. [illegible] at Newport.

[illegible] room [illegible] and [illegible] pended from the center. In the top of the umbrella was [illegible] the brackets festooned with flowers and greens. The large stained glass bay window, extending, like the ball room, to the roof, was treated in a similar manner, the ceiling having a smaller Japanese umbrella with a 100 candle power light. On the floor was a large fern tree, rising from a bed of smaller ferns, and making under the subdued electric lights a pretty picture."

That the electric light contributes greatly to man's enjoyment is evidenced by the above, but there is a Harlem man who thinks differently. To put it mildly, and not in the words of the plaintiff, Howard A. Morse has just brought a suit against the Mount Morris Electric Lighting company. An injunction will be asked to compel the lighting company to remove two arc lights which hang just beneath Mr. Morse's flat in Harlem. According to Mr. Morse there is such a thing as too much light. Two arc lamps in particular he considers are veritable instruments of torture. Shocking the servants who clean the windows, attracting into his rooms myriads of moths and other insects, the lamps must be removed. It is doubtful, then, whether Mr. Morse would be pleased to read of the Vanderbilt ball.

Detective Superintendent Byrnes did good work last night as an electrical engineer. He caught a thief by rigging up, in connection with a safe, an electric alarm. A man had been suspected, and wires were run to an electric bell in a hat store below the apartment which contained the safe. The thief at 5 A. M. made his last electrical contact, for some time to come at least, and is now probably wondering how it was done.

The Rapid Transit commission did not meet after all on Friday, Aug. 14th. A representative of the WESTERN ELECTRICIAN called at the office of the Rapid Transit commission, 22 William street, on the afternoon appointed for the meeting of the commissioners, and saw Wm. De B. Parsons, one of the two successful competitors thus far in submitting plans and specifications. Mr. Parsons would give out nothing for publication, and stated that probably no details would be made public until after the final adoption of the plans by the common council. There being present not enough members to constitute a quorum, no meeting was held.

There was a rumor last week to the effect that the construction of a rapid transit line in Broadway as proposed by the commission would vitiate the contract by which the Broadway Railroad company was given alleged exclusive privileges in that thoroughfare, in consideration of its agreement to pay the city $150,000 annually for the privilege of laying and operating a cable system. John M. Bowers, legal adviser of the commission, however, stated that there was nothing in the story. Under the conditions of its charter, he explained, the Broadway Railroad company was required to pay the city annually $40,000 in rent and 5 per cent. upon its gross income The bond referred to only guaranteed the city that the sum to be paid under the provisions of the charter requirements should not fall below the sum named. It did not matter what should be done about granting a charter for an underground railroad, the Broadway Railroad company would still be required to pay these items to the city so long as it operated its railroad.

The electric light buoys numbered "2," "4" and "6" in Gedney's channel, near Sandy Hook, are bothering the lighthouse department. Apparently the service has not been of the best, and notice was given on Aug. 14th from the Tomkinsville station that these lights would be extinguished during the time repairs were being made on the cables.

The White Squadron has sailed away. The vessels, with the exception of the Atlanta, which remains for repairs, left on Aug. 12th for a cruise along the New England coast. The Chicago carries a number of members of the Senate naval committee. F. L. P.

Omaha, Neb.

OMAHA, Neb., Aug 15.—The Omaha Street Railway company has recently commenced reconstructing its Thirteenth street line prior to changing it from animal to electric power. It is laying new Johnson side bearing girder rails and copper bonding the joints. This line will extend to the southern limits of the city. The company is building a large addition to its Nineteenth street power house, and is installing one 600 horse power Reynolds-Corliss engine, together with six 80,000 watt Edison generators. It has recently installed two 80,000 watt Edison generators of the latest design in the Harney street cable house, and [illegible] are operated by the same engine which drives the Dodge and North Twentieth street cable line. This company claims the only plant in the country where the same engine operates both cable and electric street railways.

This is the plant where the electric cars, solely by their [illegible] have driven on the cable cars from their own track. A few years go the Harney street cable line was built Now it has wholly been abandoned, so far as the cable is concerned, and nothing except the slot between the rails indicates the former use this track was put to. The electric cars glide smoothly over the rails, which needed no copper bonding, the heavy rails, yokes, etc , furnishing a most perfect return circuit.

The East Omaha electric line was recently opened. This line is about two and a half miles in length. It connects East Omaha, a manufacturing suburb, with the city. It was built by the Interstate Railway & Bridge company as a starting line for the new bridge, which is to cross the Missouri river, connecting Omaha and Council Bluffs. The motors are single reduccion Westinghouse, two 20 horse power motors to each car. The equipment at present consists of two motor and two trail cars, but this is to be increased soon. The motors are geared for twenty miles per hour, and run finely. Power is furnished by the Omaha Street Railway company to operate this line. It is expected that the "Benson line" will open shortly to an addition in the northwest part of the city. Westinghouse motors are to be used.

A. F. Blundell, who has for a long time been identified with telephone and electrical interests in this part of the country, has gone to Brooklyn, N. Y., where he has accepted a position with the telephone company.

N. Mudge, who has been conducting an electrical business for the past two years, has closed up his affairs and gone to Michigan.

Victor Poissant, an electrician of this city, has recently accepted a position with the Blue Bird Mining company, Butte City, Mont.

Electrical business is suffering from the general depression noticed all over the country. Several of the dealers and contractors say there is but little going on.

Recently in Council Bluffs it was decided to move a building along a street where the motor track was laid. There were several curves and a grade of four to five per cent , and considerable difficulty was experienced in attempting to move the building with horses. So one night, after the cars on that line stopped running, the superintendent ordered two motor cars hitched to the building, and it was rapidly drawn up the hill and out of the way of the cars.

It is stated that the motor line recently started in Lincoln, Neb., is running quite smoothly. A motor car on this system in crossing a steam railroad was brought to a standstill, its trolley flying off the wire. A freight train backing down the track struck the motor. As this train was moving slowly, but little damage was done, and nobody was injured. A.

Pittsburg, Pa.

PITTSBURG, Aug. 15.—McKeesport, Pa., will not be long without the advantages of electrical rapid transit. The dynamos and other electrical apparatus for the equipment of the McKeesport & Reynoldton Electric Railway company have arrived. The work of laying the track has so far progressed that it can be completed within a few weeks, and it is expected that everything will be ready for operation by October 1st. The Thomson-Houston company is furnishing the electrical outfit.

The Michales Electric Mining Machine company of Pittsburg, Pa , the business of which is the manufacture of machinery for use in coal mining. has made a change in its chief officer. A few days ago M. A. Michales, who has been president of the company since its organization, tendered his resignation and his place was filled by the election of William W. Grier, a well-known manufacturer of the vicinity of Pittsburg. The Michales company is now engaged in the construction of a mining plant at the coal works of O'Neil & Patterson on the Monongahela river.

The Second Avenue Passenger Railway company of Pittsburg has filed its annual report with the secretary of internal affairs at Harrisburg. During the year the road carried 1,808,993 passengers. Twelve persons were injured, but none seriously, and the accidents were all due to carelessness on the part of the injured and to no fault of the company. The receipts for the year ending June 30, 1891, were $88,492.45, the expenses being $61,094.94.

The Birmingham Traction company of Pittsburg is making an experiment upon its cars with the Genett air brake. It tried the cable brake in the first place but found it unsuited to the requirements. It is expected that the Genett appliance will work to the entire satisfaction of the management. David Reid, a representative of the Western Steam & Street Railway Equipment company of Chicago, has charge of the work.

G. Wilbur Hubley, Jr., electrical engineer, who has been for a long time in the employment of the Westinghouse Electric Manufacturing company, has just entered

the service of the Citizens' Traction company of Pittsburg and will have charge of the new electrical feeder, five miles n length, of the Citizens' company's cable line.

B. I. W.

PERSONAL.

Nelson W. Perry of Cincinnati, O., was in Chicago last week.

Louis A. Ferguson of the Chicago Edison company is enjoying his vacation at Boston.

Among the visitors at the Chicago Electric club last week was Alex. H. Lewis of Cincinnati, formerly of Chicago.

C. A. Daigh of the Electrical Engineering & Supply company has just returned from a western trip covering Minnesota, Iowa and Missouri.

W. H. McKinlock, president of the Central Electric company, is away on his well-earned vacation, and writes that he is finding both health and pleasure in the surf on the Jersey coast.

F. H. Whiting of Denver was in Chicago on Saturday last renewing old acquaintances. Mr. Whiting was for some time connected with the Thomson Welding company and later has been with an electric railway which is now being built between Denver and Golden.

A Irvine, superintendent of construction of the National Electric Manufacturing company, Eau Claire, Wis., was in Chicago on Monday returning home from an eastern trip. Mr. Irvine reports the business outlook for the coming fall season as very bright.

NEW INCORPORATIONS.

Buffalo & Williamsville Electric Railway company, Williamsville, Erie Co., N. Y.; capital stock, $50,000; to operate a street surface railroad.

Middletown Electric Street Railroad company, Middletown, Ohio. capital stock, $100,000; electric street railroad; H. Knight, Middletown, Ohio.

Electric Light, Street Railway & Power company, Creal Springs, Ill.; capital stock, $6,000; to operate an electric light plant; J. M. Eubanks, Creal Springs, Ill.

Kansas Fuel Gas company, Chicago, Ill.; capital stock, $1 000,000; to furnish electricity for light, heat and power; Loftus Edwin Daucey, 101 Auditorium, Chicago, Ill.

Edison General Electric company (of New York), Boise City, Idaho; capital stock, $12,000,000; supplying electric power and light; John W. Cunningham, Boise City, Idaho.

Flint Creek Electric Power company, Butte, Mont; capital stock, $25 000; generating electricity and using same for all purposes for which electric current may be used.

Citizens' Fuel, Light & Power company, Celina, O.; capital stock, $50,000; producing, purchasing and selling oil, gas and electric light and power, etc.; A. D. Marsh, Celina, O.

Chicago & Evanston Electric Railway company, Chicago, Ill.; capital stock, $500,000; to construct and operate a passenger street railway system; Alex. Clark, 97 Clark street, Chicago, Ill.

Georgia Electric Light company, Atlanta, Ga.; capital stock, $600,000; to manufacture, buy, sell, lease and use machinery, articles, etc, appertaining to the use or application of electricity.

Washington County Electric Light & Power company, Troy, N. Y.; capital stock, $10,000; to furnish electricity for light and power in Cambridge, Shushan and Salem in Washington Co., N. Y.

Kinsey Wright Electric Elevator company, Denver, Colo; capital stock, $25,000; manufacturing and constructing electric hydraulic, steam and hand elevators and set up and put in place the same.

Fall River Electric Gas Machine company, Rockford, Ill.; capital stock, $50,000; to manufacture and sell gas and electric lighting machinery and gas and electricity; Geo. D. Roper, Rockford, Ill.

Grand Haven Electric Light and Power company, Grand Haven, Mich.; capital stock, $50,000; to supply electric light and power to Grand Haven and Spring Lake; O. C. Mackenzie, Grand Haven, Mich.

Edison Electric Light & Power company, Fresno, Cal; capital stock, $100,000; to produce, manufacture and supply electricity for light and power, to be sold and disposed of; Frank H. Thorb, Fresno, Cal.

Pneumatic & Electric Tool company, Jersey City, N. J; capital stock, $300,000; to manufacture and sell and let pneumatic and electric tools and all improvements thereon and substitutes therefor. John Griffin, Jersey City, N. J.

Hughesville Electric Light & Power company, Hughesville, Pa.; capital stock $10,000; to supply electric light and power to the public in Hughesville, Lycoming Co., Pa.; F. H. Cheyney, 216 S. Third street, Philadelphia, Pa.

Contractors' Supply company, Chicago, Ill.; capital stock, $1,000,000; general merchandise and supply business and operating steam, heat, power, light and water supply plants; Theo. Burkhard 167 Dearborn street, Chicago, Ill.

H. Ward Leonard & Co. (incorporated in New Jersey), New York City, N. Y.; capital stock, $200,000; to carry on and supervise electrical steam, water and other engineering and construction work; Charles M. Hough, 150 Broadway, New York.

Portland & Southern Railway company, Portland, Ore.; capital stock $10,000,000; to build, buy, sell, lease, establish, maintain and operate all means of transportation, both by land and water, including horse, steam or electric lines; Ayer & Cone, attorneys, Portland, Ore.

D. & D. Electric Manufacturing company, Minneapolis, Minn; capital stock, $50,000; to manufacture and sell electric motors, dynamos, and all kinds of electrical and other machinery, apparatus and supplies, metal castings; D & D. Motor company, 327 St. Paul street, St. Paul, Minn.

Columbian Electric Light, Power, Heat and Manufacturing company, Jersey City. N. J.; capital stock, $1,000,000; to purchase, own, manufacture, operate and sell patented and other devices, compositions, machinery and systems for producing, applying and utilizing electric light, heat and power; Clinton Rice, 60 Broadway, New York City.

ELECTRIC LIGHT.

The Pass Christian, Miss, Electric Light company intends to establish an electric light plant at that place.

It is reported that a company has been incorporated for the purpose of establishing an electric light plant at Mascoutah, Ill.

The electric light plant at Bushnell, Ill., was blown to atoms by a boiler explosion recently. John Van Winkle and Charles Paul were killed.

Joseph Schrieher of Baltimore has made a proposition to establish an electric light plant in Ellicott City, Md, and it has been accepted by the city council.

At Wheeling, W. Va., the city authorities have let the contract to the Fort Wayne Electric company for the municipal electric lighting plant for $85,420.

The city council of Brownwood, Tex., has granted a franchise to the Brownwood Improvement company for the erection of an electric light plant. The contract requires the plant to be in operation within 90 days.

In Berlin, Germany, at the end of the year 1890, 4,944 arc lamps and 80,788 incandescent lamps were in use, as against 3,778 arc and 62,876 incandescent lamps in 1889, being an increase for the year 1890 of 1,166 and 17,912 respectively.

The Westinghouse Illuminating company's plant at Schenectady, N. Y., has been purchased by Samuel Insull, John Kruesi, William B. Turner, W. B Gilmore and other stockholders of the Schenectady street railroad. The same gentlemen were recently awarded the contract for lighting the streets of Schenectady by electricity.

It is expected that the electric plant of the Louisville, Ky. Gas Light company will be in readiness for operation next month. The Wood arc system is to be used. The company's contract with the city calls for the immediate supply of 165 arc lights; others to be provided as the city authorities desire. The lamps are to burn from sundown to dawn. In due time the lighting will be extended to the suburbs, when the present gasoline system will be done away with.

There has been a change in the management of the English company which supplies electricity in Madrid, Spain. Many serious complaints are being made by consumers, and some users are reverting to the use of gas. The mistake made by the company is said to consist in keeping up the price at an extravagant charge, which tends to limit the amount of business. The company could make a reasonable profit by electric lighting, even if it charged less than for gas and petroleum lighting. The price of petroleum in Madrid is five times as great as in London.

There is a man living on West Madison street, Chicago who evidently believes in reducing expenses as far as possible. or who wishes to get the greatest possible return for the taxes which he pays into the city treasury. The gentleman keeps a store, which, however, is closed during the evening. Taking advantage of the brilliant electric light from a neighboring lamp, he sits just inside the door with his back to the street and stores his mind with classic literature. Although the lamp is fully thirty feet away, its light is so powerful that the type can be clearly seen even by those who in passing glance at the page.

Referring to a statement which has been publicly made that the adoption of electric lighting in place of gas at the office of the Savings Bank Department of the General Postoffice, London, has been followed by a marked reduction in the amount of sick leave, the *Lancet* says that it has good authority for believing that the statement in question is substantially correct. Although the time which has as yet elapsed—two years—since the introduction of the new illuminant has been insufficient for the collection of trustworthy statistics, the paper named thinks that there is every reason to believe that electric lighting will prove to be much more wholesome than ordinary gas flames. An electric lamp does not compete for the oxygen of the apartment in which it is placed, and this circumstance gives it a marked advantage over any open flame.

ELECTRIC MOTOR.

The draw on the new Harvard bridge which spans the Charles river at Boston and Cambridge is to be operated by electrical power. A six horse motor will be utilized.

ELECTRIC RAILWAYS.

[illegible] electrical railroad at Alexandria, Va.

The survey for the Florence, Ala., electric street railroad [illegible]

[illegible] power plant.

[illegible] stallation is described as including eight arc and 2,653 incandescent lights.

[illegible] car lines of Alton, Ill., have determined to combine under one system, and to operate by electricity. The improvement will cost about $40,000, and will be completed in September.

Thomas Lowry of Minneapolis has written a letter to the Edison company on the published statement that the Edison motors were being replaced by others in which he says: "There is no truth whatever in the statement. We are using the motors and they are giving satisfaction."

The city of Bremen will probably soon enjoy the distinction of being the first German city in which horses will have been wholly supplanted by electric power for street car service. A part of the Bremen street car system has been worked electrically for some time, having been equipped by the Thomson-Houston company and now arrangements are being made with this company to fit up the whole Bremen system.

A contract for an electric railway to be installed in Brazil, says the *American Manufacturer* of Pittsburg, has been taken by Benjamin Blum, who will send a sample installation consisting of one car with 25-horse power motors; one 50,000 watt generator and all station apparatus and entire equipment for one and one half miles of track. This is for a narraw guage road, and if successful the entire road is to be equipped by Mr. Blum.

On August 13th the sale of the Belle City street railway of Racine, Wis., was consummated. The purchaser was C. H. Holmes, who represented a St Louis syndicate, and it is said that the consideration was between $75,000 and $90 000. The new company will, it is asserted, expend $200,000 in extending the line and putting in an electric system next year. The property consists of seven miles of track, twelve cars, real estate and the franchise.

Julian Ralph, the well-known New York correspondent, in a letter in the [illegible] says "In the streets of Minneapolis I found several lines of electric surface railway, all of which were better than either our elevated railways or our horse cars; more frequent, numerous, fast, commodious and pleasant than any vehicles in New York. The cars are propelled by the overhead trolley system and are run in couples. They are open at the sides, and are wide and handsome."

ELECTRIC MINING.

The new power house at the Winter Quarters coal mines near Salt Lake City, Utah, is nearly ready for the roof, and the electric locomotive is on its way from the manufacturers. It will be run by a trolley system, and haul the dump cars of coal through the mines and to the chutes, where they will be loaded on the cars. The stationary engine and boilers are on the ground, ready to be set up, and the dynamos have arrived, so that the entire establishment should be ready for operation by the 1st of September.

TELEPHONE.

There are now 4,400 subscribers attached to the telephone central station in Friedrichstrasse, Vienna.

It is stated that the Austrian government intends to take charge of all telephone lines conceded to foreign companies as fast as the present concessions expire.

The Clifton Forge & Covington Telephone company of Covington, Va., has been organized with J. M. Buck president; J. W. C. Bryant, vice-president, and G. T. Shepperd, secretary, for the purpose of constructing telephone lines.

TELEGRAPH.

A new cable to the West Indies is among the [illegible] ties. F. N. Gisborne, official electrician to the government of Canada, has recommended the construction of such a line after visiting the West Indies and collecting statistics as to the volume of business that may be expected from each island. His report has been submitted to a London syndicate. The line recommended will be an extension of the cable between Halifax and Bermuda [illegible] will terminate at Demarara, touching on its route Forture Island and the Island of Jamaica and passing through the Caicos passage.

MISCELLANEOUS.

It is said that the small quantity of water that can be eliminated from ordinary [illegible] can be removed by electrolysis, being decomposed into oxygen and hydrogen before the acid itself suffers change. In order to avoid the decomposition that might occur, M. Leon has recently patented a process in which [illegible] electrodes of large area, kept cool by the circulation of water through them, are used. The acid itself is also cooled.

TRADE NEWS.

[illegible] stated in these columns a [illegible] with very gratifying [illegible] and chiefly a considerable number have been sold by the Central Electric company.

[illegible] general manager of the light and power department and also of the intelligence department of the Edison General Electric company, resigned on August 3d, in order to start an independent electrical engineering business. Mr. Leonard will take with him several well tried assistants, among them A. St. C. Vance, E. H. Harrison, C. H. Bloomer and August Munning. The company give particular attention to the subject of the transmission of power by electricity and the application of electric motors to the operation of special machinery. Mr. Leonard's experience since 1883, when he became a member of Mr. Edison's first electrical engineering staff, has given him experience in every branch of electric light and power work. He has had experience in exploiting as well as constructing and operating all kinds of electric light and power plants. An interesting feature of the business will be the intelligence department.

The Stanley Electric company's shops on Clapp avenue, Pittsfield, Mass., are very interesting to visitors. This is Pittsfield's youngest industry. There are now employed at the factory about eighty hands, including several women who have light work to do. On the first floor the Stanley converters are made. The company has just made on a special order what are claimed to be two of the largest converters ever manufactured. They are wound each for a primary current of 3,000 volts. They are to be used on Long Island, where the current is carried ten miles. At this point other converters reduce the current to 1,000 volts, and it is then ready for further distribution. Though compelled to meet with very spirited competition, the company has held its own from the first, and is constantly behind its orders. From 30 to 60 converters are turned out each week, and the firm of Jones, Sons & Co. of Pittsfield, who do the castings at a foundry across the street, finds quite a sizable addition to its business. On the second floor of the building the company makes the fan motors. About 50 of these little machines are made every day. The prosperity of the company is a matter of rejoicing to every citizen

BUSINESS.

The Metropolitan Street Railway company, of Macon, Ga., has recently ordered from the Ball Engine company, of Erie Pa., a complete plant consisting of a 150 horse power tandem compound engine, boiler and heater pump. Dravo & Black, the Pittsburg representatives of the Ball Engine company of Erie, Pa., have sold the Braddock Street Railway company, of Braddock, Pa., a 100 horse power Ball engine, also boiler, heater, pump, etc. They have also sold the Pittsburg Plate Glass company two 150 horse power Ball engines.

E. F. Van Ness & Co. of Valparaiso, Ind., have arranged to install an electric lighting plant, and have purchased their machinery, including two steel boilers and an Armington & Sims engine. This order was placed with the Chicago office of the Pond Engineering company. The Salt Lake City Power, Light & Heating company has found it necessary to make a large increase in its power plant, and has ordered two additional Armington & Sims engines from the Pond Engineering company. St. Louis. The Sioux City Gas Light company of Sioux City, Ia., is making some extensive changes in its power plant, and will put in two large Armington & Sims engines. This company has been using a 400 horse power engine of this make for some time past. The Pond Engineering company of St. Louis has the order for this additional work.

ELECTRICAL PATENTS.

Issued Aug. 11, 1891.

457,334. Pole Trolley and Stand for Electric Street Railways. Thomas E. Adams, Cleveland, Ohio.

A sliding grooved shoe is employed, the shoe or shoes being held in contact with the conductors by [illegible]

457,[illegible] [illegible] Henry H. Eades, Detroit, Mich.

457,[illegible] [illegible] Henry H. Eade Detroit, Mich.

457,343 Magnetic Belting. Thomas A. Edison, Llewellyn, N. J.

[illegible]

457,[illegible] [illegible] York, N. Y.

[illegible]

Cyprien O. Mailloux, New York, N. Y.

This invention consists, essentially, in sleeving the driving motor upon a shaft or bearing parallel to the driven axle, but preferably upon the driven axle or shaft itself, and interposing an eccentric sleeve between the motor bearings and the shaft or axle, said sleeve being combined with means whereby it may be adjusted circumferentially about the shaft or bearing and set in any particular position, thereby moving the motor frame and armature shaft bodily, so as to move a member of the gear train carried by said shaft to or from its opposite member, which is connected directly or indirectly with the axle upon which the motor is sleeved.

457,362. Electric Steam Generator and Heater. Willis Mitchell, Malden, Mass.

457,374. Safety Device for Electric Wires. John H. Sedlmeyer. Johnstown, Pa.

457,377. Trolley for Electric Railways. S H. Short, Cleveland, Ohio.

457,378 Trolley. S. H. Short, Cleveland, Ohio.

457,382. Electric Railway. Michael H. Smith, Halifax, Eng.

In this invention the negative and positive conductors are arranged in different horizontal planes, preferably with one conductor directly over the other. and while it is not necessary to use more than a single positive and a single negative conductor in some instances it has been found preferable to make use of two positive and two negative conductors, the positive and negative conductors being arranged in separate horizontal planes.

457,407. Self-Regulating Electric Converter. Thomas Spencer, Pittsburg, Pa.

This invention consists in placing upon the core a few convolutions of secondary wire wound in the reverse direction from the main portion thereof and in locating these convolutions so that the escaping lines of force do not thread them. From this construction it results that when but little current is flowing in the secondary, and consequently but little opposition is offered to the flow of the lines of force through the core, practically all these lines of force thread both the main and the reversed secondary convolutions.

457,430. Electric Battery. Flavien Poudroux, Paris, France.

457,453. Electric Meter. Eugene Maylan and Wencelas Camille Reckneiwski, Paris, France.

457,454. Annunciator. Walter R. McCann and Simon S. Creider, Sterling, Ill.

457,457. Electric Oil Well Heater. Charles W. Robinson and Samuel D. Robinson, Allegheny, Pa.

This invention is utilized by inserting into the well an electrically heated coil or high resistance conductor, and, when it is at the oil bearing strata, passing through it a current of electricity, by which it is heated, so that it may communicate its heat to the well. The nature of the heating coil and of the electric current supplied thereto should at least be such that sufficient heat is generated to fuse paraffine.

457,477. Automatic Telephone System. Hammond V. Hayes, Cambridge, Mass., and Henry D. Sears, Lynn, Mass.

The object of this invention is to furnish a system of intercommunication for such places as are unable to sustain a regular central station organization, whereby in its operation each sub-station in the system shall be enabled to place its own line in connection with any other line converging to the same point; to send call signals to the desired sub-station over the compound line thus formed without in any degree impairing the connections thus established between the two lines constituting the component members thereof, and upon the completion of the communication to restore the original normal or resting condition of both of the lines. An additional object of this invention is to accomplish these operations without any other sub-station apparatus than that in ordinary use and without material change in the construction of the apparatus, and, furthermore, with central station apparatus of the most simple character compatible with absolute certainty and accuracy of operation.

457,483. Automatic Electric Circuit Switch. William L. Silvey, Lima, Ohio.

The object of this switch more especially is to open the external or electrical circuit of a street railway system whenever by any cause the conducting wires shall become crossed or short circuited. The object is to prevent an overplus of current in the crossed circuit, thereby endangering the armatures of the generators attached to the line by reason of the overplus of current generated on the instant of closing the circuit.

457,[illegible] Electric Motor. W. S. Hill, Boston, Mass.

Claim one describes an electric motor, the field magnets of which are composed of plates of sheet metal clamped between the end plates, recesses in said plates and rods having reduced ends passing through the sheet metal plates and end plates and secured by [illegible] the whole being clamped together.

457,[illegible] Electrode for Secondary Batteries. Leonard [illegible] York, N. Y.

457,561. Apparatus for Heating by Electricity. Rankin [illegible] Montreal, Canada.

[illegible] to that class of apparatus in which the electric energy is to be converted into [illegible] by the action of magnetism, which is generated by deriving from any suitable electric generator electric currents, preferably of an alternating [illegible] and by so arranging the [illegible] that magnetism may be applied directly thereto and the heat produced within its substance. Smoothing irons, soldering irons, and other tools and utensils of similar character are heated by placing them against or between the poles of an electro magnet, preferably provided with a laminated iron core and energized by a current, preferably alternating in its character. The magnetism is induced within the iron utensil under the influence of the alternating currents within the mass of iron of which the articles are constituted, so that the whole energy of these currents is transformed into heat within the iron.

457,565. Signal Telegraph for Cable Railways. Theodore A. B. Putman, New York, N. Y.

The object of this invention is to provide a signaling telegraph by means of which an alarm may be given in the power house by the driver of any of the grip cars whenever he finds that he can not release his grip. By this invention the signal can be given by the gripman without leaving his post and without a moment's delay, thereby saving every available second of time at an instant when even a slight delay may result in a serious accident.

457,572. Switch. S. Bergman, New York, N. Y.

457,573. Means for Suspending and Controlling Electric Lamps. S. Bergman, New York, N. Y.

457,657. Wind Apparatus for Generating Electricity and Charging Secondary Batteries. James M. Mitchell, Lawrenceville, Ga.

This invention relates to apparatus whereby wind power may be applied to operate a dynamo electric machine for the purpose of generating a current which may be utilized in charging a secondary or storage battery to supply lighting, motor and other circuits.

457,660. Hanger for Trolley Wires. Nelson Newman, Springfield, Ill.

457,687. Electric Light Hanger. Frank A. Weimer, Stanberry, Mo.

This invention consists in forming the flexible conducting cord around a core of steel or other spring material, and then winding the so formed cord like a spiral spring, the core having sufficient elasticity to permit it to be streched or drawn out far enough to allow the lamp to be carried from place to place in the room or hall or even from one room to another and at the same time having sufficient strength to return and hold the lamp in its original position when the latter is brought back.

457,736 Electric Railway. Rudoph M. Hunter, Philadelphia, Pa.

Claim one describes a conduit for an electric railway, provided on its upper portions with lateral flanges formed integral with the side walls, said flanges being provided with drainage apertures, in combination with working conductors located within and insulated from said conduit.

457,745. Electrically Heated Oven. Willis Mitchell, Malden, Mass.

This invention has for its object to increase the efficiency of electrically heated ovens and to protect and insulate the heating wires more effectually and easily than hitherto. For these purposes the bottom, top and sides of the oven are made with successive layers of asbestos or other insulating material, the heating wires being wound around the interior space in successive coils or layers and practically imbedded therein.

457,754. Dynamo Electric Machine or Motor. Edward M. Warning, Brooklyn, N. Y.

In general terms this invention consists of two field magnets arranged one upon each side of the armature concentric with the armature shaft or axis of rotation, the pole pieces of each system being connected together to form consequent poles, the whole structure forming a cage inclosing and protecting the armature and commutator.

457,761. Connection for Electric Conductors. Joseph Dillon, Larchmont, N. Y.

This invention provides a case or shell for inclosing the joined ends of the conductors with parallel openings through which the ends of the cables or sheathed wires or groups of wires are thrust, and into which they are fastened in a manner both rigid to resist mechanical flexure and impermeable to air or moisture. The case or shell is constructed with a cap or cover, which can be applied and removed independently of the connection of the cable ends in said openings. The ends of the conductors in the case are bared of insulation and, being arranged parallel with each other, are electrically connected by applying to them a bridge piece of copper or other conducting metal, the ends of which clasp the bared wires, and are preferably soldered to them.

457,762. Electric Air Pump. Allen A. Dittmar and Hugo Falkenhausen, New York, N. Y.

Claim one describes an electric air pump, suction and discharge compartments communicating with the pump cylinders by valve openings, in combination with solenoids placed over openings in the top plates of the compartments and having movable cores which pass through the openings in the said top plates and act as valve stems, so as to open and close the respective valve openings by electric currents conducted alternately through the respective solenoids.

457,763. Electric Light Carbon. William P. Eltringham, Dubois, Pa.

The object of this invention is to prolong the life of the carbon sticks, especially those used in arc lights, so as to do away in a measure with frequent renewals, and it consists in heating or tempering the carbons by the use of borax, or any equivalent of borax either during the process of manufacture of said carbons or afterward.

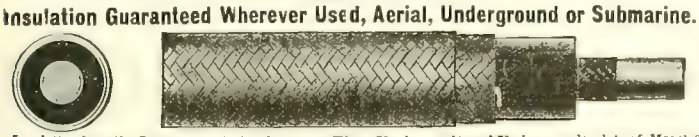
THE "CLARK" WIRE.

Insulation Guaranteed Wherever Used, Aerial, Underground or Submarine.



In a letter from the INSPECTOR of the **Boston Fire Underwriters' Union**, under date of March 29, 1886, he says: **"A Thoroughly Reliable and Desirable Wire in Every Respect."**

The rubber used in insulating our wires and cables is specially chemically prepared, and is **guaranteed to be waterproof, and will not deteriorate, oxidize or crack**, and will remain flexible in extreme cold weather and not affected by heat. The insulation is protected from mechanical injury by one or more braids and the whole slicked with Clark's Patent Compound, which is water, oil, acid and to a very great extent, fire-proof. **Our insulation will prove durable when all others fail.** We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph, Telephone and Electric Lights from stock. Cables made to order.

From every station selected an *Automatic Answer Back* is received.

Gong rings until shut off by operator.

Any office on line can be selected without disturbing the others and either called up or cut out. No interference with regular telegraph service. No resistance added to main line. Easily applied. Economical. Convenient. Reliable.

Applicable to arc lights, singly or in groups; fire alarm service; police telegraph; electric motor circuits; railroad signals, etc.

The public is warned against infringing companies and dealers.

For terms and other particulars, address as above.

"WARD" ARC LAMPS,

FOR CONSTANT POTENTIAL CIRCUITS.

THOUSANDS IN USE

On both Isolated and Central Station Plants.

WE GUARANTEE OUR LAMPS ELECTRICALLY AND MECHANICALLY.

In corresponding please give full particulars and state voltage.

ELECTRIC CONSTRUCTION AND SUPPLY COMPANY,

Phenix Bldg., CHICAGO, ILL. 18 Cortlandt St., NEW YORK CITY.

ESTABLISHED 1881.

ELECTRICIAN PUBLISHING COMPANY'S

HAND-BOOK SERIES.

22,000 Copies published to date. An Astonishing Record.

Dynamo-Tenders' Hand-Book.

By Lieut. F. B. Badt.

Fourth Edition, Eighth Thousand.

94 Pages, 70 Illustrations, Flexible Cloth Binding, Type Page 6x3 inches.

The only PRACTICAL Dynamo-Tenders' Instruction Book in the English language. Just the book for Dynamo-Tenders, Linemen, Stationary and Marine Engineers who wish to learn how to operate and care for electric light or power plants. Moonlight schedule for 1891.

Bell-Hangers' Hand-Book.

By Lieut. F. B. Badt.

Second Edition, Fourth Thousand.

106 Pages, 97 Illustrations, Flexible Cloth Binding. Type Page 6x3 Inches.

Designed for those engaged in selling, installing or handling electric batteries, electric bells, elevators, house or hotel annunciators, burglar or fire alarms, electric gas lighting apparatus, electric heat regulating apparatus, etc. The only book of the kind published.

Incandescent Wiring Hand-Book.

By Lieut. F. B. Badt.

Third Edition, Seventh Thousand.

72 Pages, 42 Illustrations, Flexible Cloth Binding. Type Page 6x3 Inches. Five Tables, 12x18 Inches.

These tables give *at once* and without any calculation the size of wire required in each case for any percentage of loss.

It is a book for practical wiremen and learners, and does not require any previous knowledge of wiring. It differs in this respect from other wiring tables, or computers.

The book contains full illustrations and complete information concerning methods of running wires, location of safety devices, splices, insulation, testing for faults, wire gauges, wiring of fixtures, elevators, buildings, etc. The only book of the kind published.

Electric Transmission Hand-Book.

By Lieut. F. B. Badt.

First Edition, Three Thousand Copies.

97 Pages, 22 Illustrations, and 27 Tables. Flexible Cloth Binding. Type Page 6x3 Inches.

This book contains all practical information for power-producers, capitalists, agents of hydraulic and electric companies, engineers, motor inspectors and other persons interested in electric power transmission. By means of the tables anybody can find at once cost of plant for least operating expenses, or for minimum first cost of installation.

The book gives all necessary information concerning motors, and rules for ascertaining horse power of motors, driving various classes of machinery, as hoists, pumps, street or tram cars, fans, etc.

Twenty-seven new and original tables give more information on the subject in a small space than any book heretofore published on the same subject.

Each Work Sent Postpaid on Receipt of One Dollar.

ELECTRICIAN PUBLISHING CO.,

6 Lakeside Building, CHICAGO.

FORT WAYNE ELECTRIC CO.,

FORT WAYNE, IND.,

—MANUFACTURERS OF THE—

SLATTERY INDUCTION AND WOOD ARC SYSTEM

—OF—

ELECTRIC LIGHTING.

THE MOST PERFECT OF ANY.

For references as to the merits of these systems, inquire of the local companies, the operators, or the customers in the large cities of this country where these systems are now being used almost exclusively after other systems have been tried and thrown out—Philadelphia, New Orleans, Cincinnati, St. Louis, Kansas City, Louisville, Detroit, etc.

WE MAKE ALL STANDARD SIZES OF

INCANDESCENT LAMPS FOR THE ALTERNATING SYSTEM.

Also Arc Lamps of Standard Sizes, 2,000 c. p., 1,200 c. p. and 800 c. p.

Main Office and Factory, FORT WAYNE, IND.

GENERAL ELECTRICAL INTELLIGENCE BUSINESS.

Under the above heading we have considered a very important feature of our business, which will be entirely unique and commendable. To any Isolated Plant we offer, at a very moderate subscription price ($25.00 a year), the privilege of corresponding upon any electrical subject of practical interest. Thus, an isolated plant will be able to secure expert information as to its own plant, the best methods of operating it, and about any new electrical apparatus or methods and the principles underlying various devices and the prices thereof. For Central Station Companies, whose queries would go further into Steam Engineering and methods of distribution and also would cover business questions as to relations with consumers, systems of accounts, etc., the annual subscription charge for this electrical intelligence will be $50.00.

In case the expert judgment of the Company be desired as to comparative merit of various competing apparatus or methods, such expert judgment will be given by special arrangement although the Company prefers to merely supply full information under the subscription arrangement and allows the purchaser to form his own conclusions.

SUBSCRIPTION CONTRACT.

H. WARD LEONARD & CO.

GENTLEMEN:—Please enter the subscription of the undersigned for such electrical information as may be requested of you, subject to the following conditions:

FIRST.—The subscriber shall have the privilege of calling for any information which he considers may be of practical value to him in the operation of his plant.

SECOND.—All queries shall be by correspondence only.

THIRD.—H. Ward Leonard & Co. shall not be called upon under this yearly subscription to give its expert judgment on the comparative merit of various apparatus or systems, but shall furnish full descriptive information regarding the character, principles, methods, forms, catalogues, prices, etc., involved by the questions as far as they are able to.

FOURTH.—All information supplied to the subscriber shall be confidential and for his information only.

FIFTH.—This subscription shall be for one year from date and at the rate of Twenty-five dollars per year.

Signed, ...

The usual subscription is by the year. To enable subscriber to judge of the merits of such a plan, we will make the following special offer:

To all parties signing the above subscription contract and returning same to the Company promptly, it will agree that the date of expiration of the contract is December 31st, 1892.

To parties other than Isolated Plants and Central Stations, special quotations will be made for these services on application. Address

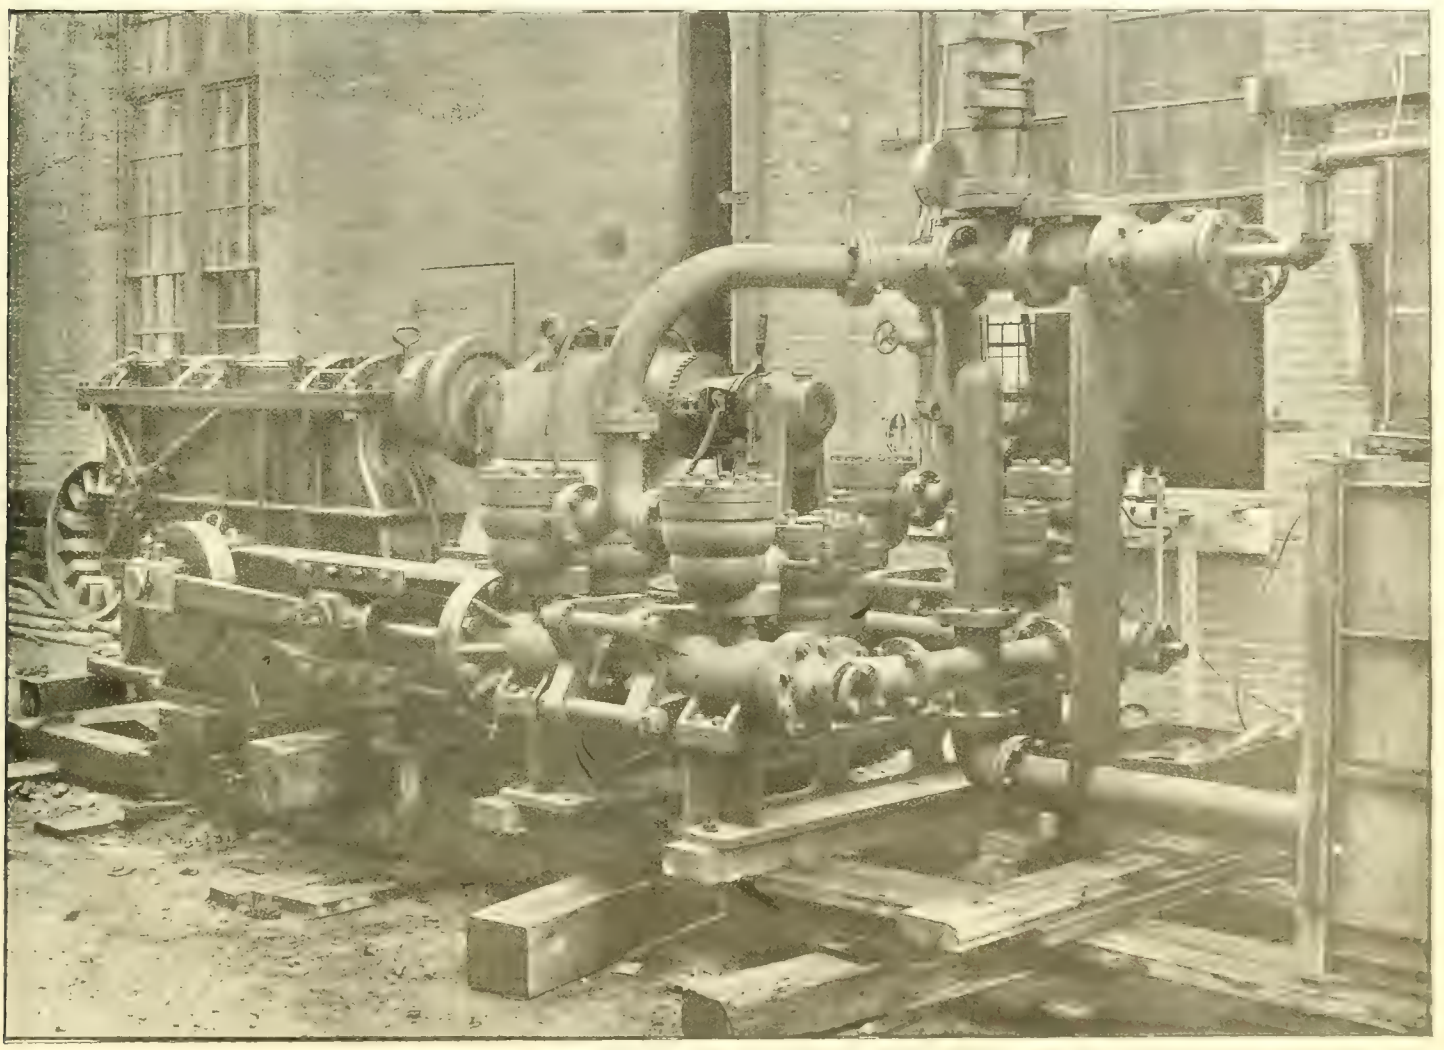
Vol. IX. CHICAGO, AUGUST 29, 1891. No. 9

Largest Electric Pump in the World.

The imposing mass of machinery illustrated in the accompanying picture possesses a peculiar interest from the fact that it is believed to be the largest electric pump in existence. It is only within the last three or four years that mine proprietors have awakened to the many notable advantages possessed by electricity over other methods of transmitting power to mining machinery. Now, however, the idea has taken a firm foothold, especially in the United States, and the installation of electric mining plants promises to become one of the most important features of the business of the electrical manufacturing companies. Of machinery of this character pumps operated by electric motors are especially useful, and the one shown in the illustration is undoubtedly the most powerful that has thus far been made.



LARGEST ELECTRIC PUMP IN THE WORLD.

This machine has been built by the Thomson Van Depoele Electric Mining company for an iron mine at Iron Mountain, Mich. It is operated by a 60 horse power motor geared to the crank shaft of the pump by a worm gearing. Its capacity is 100 gallons per minute against a head of 1,400 feet at one lift. The generator is of 80 horse power capacity and will be located about 3,000 feet from the pump, the latter being employed, of course, to keep the mine clear of water. Copper conductors will be used, calculated for a loss of five per cent. in the line. The details of the wiring and insulation, however, have not yet been determined.

This interesting installation is in charge of the western power and mining department of the Thomson Houston company, at Chicago. The pump has not yet been put in actual operation at the mine, and the photograph shows it mounted for testing at the company's factory. A more detailed account of its working will be given later.

Electricity at the World's Fair.

A substantial victory for the committee on electricity and the electrical department was achieved at the meeting of the executive committee on the 19th. This committe is composed of the chairmen of the other committees and is vested with great authority. After discussing the conflict of authority between the committee and department of electricity and the department of construction the executive committee adopted a resolution directing the grounds and building committee to allow the chief of construction to enter into no negotiations for light or power plants without the approval of the committees on electricity and machinery. Of course the committee on grounds and buildings will make the awards for all contracts, as usual.

In commenting on this move the *Tribune* says:

This action means two things. First, that the committee on electricity intends to know what is going on in matters presumably under its jurisdiction; and, second, that Chief Barrett of the department of electricity will have considerable to say about the character of the electric power and lighting plant for the exposition. It means also that considerable restriction will be placed on Chief of Construction Burnham, and that he will have to secure the advice of department chiefs in reference to this particular matter. The action is right in line with the [illegible] trol to the effect that department chiefs should have almost exclusive jurisdiction in the installation of exhibits. As it is intended that the power plant shall be installed as an exhibit, there is nothing left now for the chief of construction to do but advise with the chiefs of machinery and electricity as to the character of the power plant.

"While this action curtails the authority of Mr. Burnham," said a member of the committee on grounds and buildings, "it was not done in a spirit of antagonism. We have an experienced man for chief of the department of electricity, and expect to have an efficient man for the department of machinery. We shall have to pay them salaries for [illegible] that since they are our employes we might as well secure the benefit of their experience and knowledge."

It was through the wish of the committee on electricity that the resolution mentioned was carried, and as that committee thinks well of Chief Barrett and has practically been championing his cause, it is not unlikely that he will be made the committee's adviser and so become a most important factor in the placing of the electric light and power plant.

The adoption of this resolution will certainly go far toward the establishment of a definite understanding in relation to disputed questions of authority between the departments of electricity and construction, for which the WESTERN ELECTRICIAN has contended. It is to be hoped that this decision, as the first step, will lead to a complete adjustment of harmonious relations. The committee on electricity, which is in accord with the [illegible] of the same name, has obtained recognition of [illegible] trical machinery that may become a [illegible]

cannot be installed without its authority. The power of both parties to the controversy is thus defined and limited, and there should now be but little difficulty in arriving at a complete understanding.

On Saturday of last week the committee on grounds and buildings formally adopted the resolution which the executive committee instructed it to pass. The language of the resolution is as follows:

Resolved, that the grounds and buildings committee hereby instruct the chief of construction to first obtain in writing the concurrence of the committee on electricity, electrical and pneumatic appliances on all matters pertaining to electricity, electrical and pneumatical appliances, and all plants connected therewith, before submitting the same to the grounds and buildings committee for action.

This settles one important question that has been in controvery between the departments of electricity and construction in favor of the former.

It is said that one million five hundred thousand feet of lumber has been delivered for the electricity building, and nearly one-half of the foundations of the structure are completed.

The grounds and buildings committee will probably abolish the "loop" of railway tracks entirely, together with the circular "machinery annex," the design of which is now said to be preposterous. The "stub" terminal system will undoubtedly be adopted at Chief Burnham's suggestion, and the annex will probably be a square building west of Machinery hall. This subject is one of much interest to electricians, as the big power house for the generators will undoubtedly be adjacent to the "annex," wherever that may be located.

The contract for roofing the electricity building has been awarded to James A. Miller & Bro. of Chicago for $22,100.

On Thursday of last week Secretary Hornsby received the detail plans of the electrical building from the construction department. Under the direction of Chief Barrett the secretary will be required to indicate as nearly as possible the location of the aisles and the space to be devoted to these passageways. It is proposed to lay railway tracks on the ground in the building, before the floor is laid. The heavier exhibits will then be brought directly into the structure on the cars and transferred to the place designated for them by huge electric cranes. The flooring will hide these transportation tracks from view before the building is open to the public, and the same means of taking the machinery away will be made use of after the exposition is closed.

The [illegible] has heard of a marvelous microscope, with electrical attachments, to be shown at the Chicago exposition by the Munich Poeller Optical institute. The instrument is said to have cost nearly $9 000, [illegible] a magnifying power of 11,000 diameters. The electricity furnishes and regulates the source of light, which, placed in the focus of a parabolic aluminum reflector, reaches an intensity of [illegible] The [illegible] provides the means of an ingenious automatic mechanism for the centering of the [illegible] and illuminating the lenses. There is an arrangement for the exact control of [illegible] is the cooling machine, which is indispensable on account [illegible] The apparatus with ordinary objectives, as has been stated, is about 11,000 diameters, but with the oil immersion it can be increased to 16,000."

A Paris newspaper publishes a ridiculous statement to the effect that the great feature of the opening of the exposition will be the electrocution of six people, "two of whom are innocent."

Electric Light Plant on the Virginia.

Much attention has been attracted to the handsome new passenger steamer, the Virginia, plying between Chicago and Milwaukee, on the Goodrich line. The Virginia arrived in Chicago, glistening in her new dress of white paint, and manned by a full crew of sailors, who were proud of their fine new uniforms, and prouder still of the gallant ship, under whose colors they were to serve. The new boat is said to be more complete in her appointments than any other on the lakes.

The steamer was constructed by the Globe Iron Works of Cleveland, Ohio. The dimensions of the hull are 278 feet over all, 260 feet keel, 38 feet beam and 25 feet deep. The water bottom is separated into six sections, and contains a tank of 4,500 gallons capacity. Her gross tonnage is 2,500, and her carrying capacity 750 passengers.

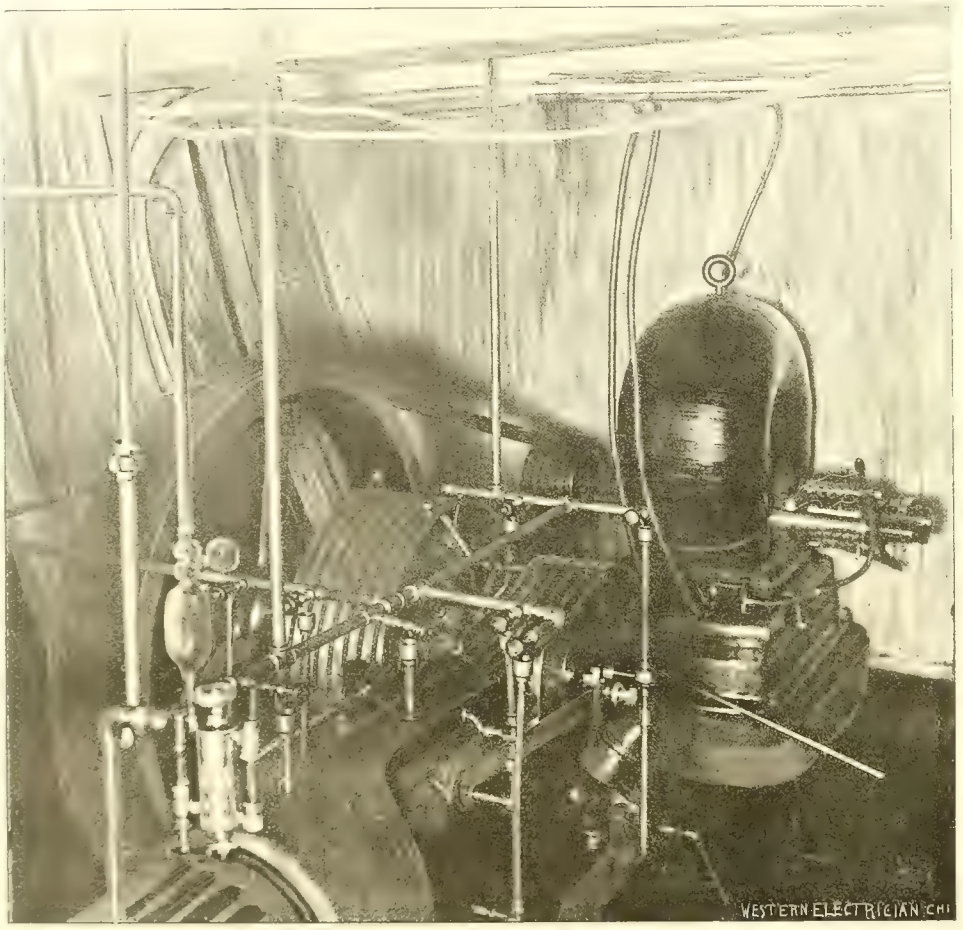


FIG. 1. ELECTRIC LIGHT PLANT ON THE VIRGINA.

The advent of the steamship Virginia marks a new era in the construction of boats for lake transportation. While ocean steamers have been provided with first-class accommodations and even luxurious fittings, little attention has been given this matter in the construction of lake craft. The Virginia is modeled after the finest of ocean steamers, and consequently lacks nothing conducive to the comfort and care of her patrons. She is the first Chicago passenger boat equipped with twin screws. The screws are 11 feet in diameter. In addition to this feature she excels in her electrical equipment, which is undoubtedly finer than that of any other lake steamer.

The boat is provided with double cap mouldings, and is wired in duplicate, there being about 700 lamps—of these about 12[illegible] are used for lighting the large dining salon. This room deserves special mention. The sides are finished in rich mahogany, and the prevailing tone of decoration is ivory and black. The lamps are lavishly distributed about the handsomely paneled ceiling. The main cabin, state rooms and other apartments are all furnished with [illegible] taste and [illegible].

The dynamo room, separated into two compartments, each [illegible] feet in size contains two 500-light compound dynamos of the Mather type. Fig. 1 shows one compartment of the dynamo room, with dynamo and 100-horse power Beck engine. Fig. 2 shows the switchboard, which is placed in a convenient position between the two compartments of the dynamo room. A 35,000 candle power search light, which is soon to be placed on the boat, will complete the electrical equipment. The lamp fixtures are all of the finest workmanship. They were especially designed and made for the Virginia by the Chicago Gas & Electric Fixture company. The Chicago branch of the Mather Electric company had charge of the electrical equipment and installation.

Electricity on Our Great Railways.

HUBERT S. WYNKOOP, M. E.

On May 4th Frank L. Perry read a paper before the Chicago Electric club on "Substituting Electricity for Steam, from the Standpoint of the Steam Railroad Man." In the discussion that followed Lieutenant F. B. Badt made the following statement, which I shall take as my text: "It seems to me that it is not a question between steam and electricity as to the speed at which we shall travel, but simply the question of construction of tracks; *and that we can obtain a much higher speed with steam if we can only construct tracks in accordance with his* (O. T. Crosby's) *ideas.*"

In order to prove that the adoption of tracks of new and improved design will have no bearing upon the question of steam railway speeds, I shall assume throughout this discussion an ideal road bed, or one free from heavy gradients, sharp curves and grade crossings.

The word "speed," as applied to railway travel is so ambiguous that I shall discard it entirely, substituting therefor either "velocity" or "endurance" to express the rate of motion at any given instant or the average rate of motion for an hour. A few interesting facts will clearly demonstrate the distinction between velocity and endurance.

In the spring of 1885 locomotive No. 169 of the Central railroad of New Jersey, with 5 feet 8 inch coupled drivers, hauling four coaches, containing 65 passengers, touched a velocity of 80.33 miles per hour on a level track going east through Crawford, N. J. (The same engine is credited with a velocity of 84 miles an hour, but in the absence of any authorized report I shall not use this figure in the discussion.) In 1888 John Wolff, M. E., and the writer tested locomotive No. 171 of the same road. With five well filled coaches going west through Dunellen, N. J., down a gradient of one in 260, the highest recorded velocity was 78.89 miles per hour, the velocity figures as calculated from the number of revolutions and the diameter of the drivers tallying closely with results obtained by noting time between mile posts by means of a stop watch, when the acceleration was zero.[1] Searching English records for velocity figures, we read in London *Engineering* for June 29, 1888, the following: "The highest speed ever known to have been attained in this country is recorded of the ten-wheeled tank engines with nine feet single driving wheels, built for the Bristol and Exeter line in 1852, which actually touched 80 miles an hour, with no load, down a gradient of one in 89, and 78 miles an hour on a level with two coaches." Contrast the size of drivers and weight of cars in England with those in America, and note how much swifter is the American locomotive.

I have just adduced figures proving the superiority of our locomotives over those in England in the matter of velocity; and, if I shall by the aid of figures show that English locomotive haul trains at a higher average velocity or endurance than ours do, it will at once become evident that my determination to discard the word "speed" was

1. It might be well to mention here that the [illegible] driver [illegible] engine at high speeds, [illegible] H. W.

advisable. For illustrations of endurance we may again refer to London *Engineering*. "Mr. Martin records three splendid runs at which a sustained speed of about 60 miles an hour was kept up, with the Great Northern Manchester express between London and Grantham he twice covered 100 miles in 103 minutes, and on the Great Western between Swindon and London 72 miles in 71 minutes, the engine in each case being an eight feet single driver. With a Midland seven feet coupled engine having nineteen inch cylinders he traveled fifty miles an hour, and the same was done in a train drawn by a London & Northwestern 'Precedent.' Although these are somewhat exceptional examples, yet there are in summer no fewer than 105 runs timed to make daily from start to stop at an average speed of fifty miles an hour and upward. The highest average speed at which a train is timed from start to stop is just fifty-four miles an hour. This is the Great Northern Manchester up express, which performs the longest run in the world without a stop[1]—105 miles 26 chains—to be done in one hour 57 minutes. The Great Western Exeter express s stand third with 53¼ miles an hour. Over the first 77 miles out of London the down trains and one up train are timed at this speed. The Great Northern has no fewer than seven trains, and the Great Western three, timed at an average running speed of over fifty-three miles an hour between stopping stations. Besides these there are in the country twenty-five trains at fifty-two to fifty three miles an hour, twenty-seven at fifty-one to fifty-two, and forty at fifty to fifty one miles an hour, running time. It is no wonder, in the face of these speeds, that locomotive engineers are feeling in all directions to get engines of greater power. Mr. Webb is going in boldly for the compound system, and appears to be getting splendid results out of it. Mr. Worsdell is also adopting the compound system— worked out in another way—very freely, while others are waiting to see the results. *On our great competing lines we have come to the limits of the capacity of the ordinary locomotive* whatever the form it takes and if trains are to be increased in weight, or speed to be materially augmented, some new departure must be made."

In America we have as yet been unable to obtain such endurance. Numerous grade crossings, heavy gradients, new and shaky track, and exceptionally heavy cars conspire to make our road beds far inferior to those in England, which approximate closely the ideal.

The Pennsylvania railroad runs its Congressional Limited from Jersey City to Washington, 227 miles, in five hours two minutes, or 45.04 miles per hour. The Chicago Limited of the same line covers the distance from Jersey City to Pittsburg, 443 miles, making four stops, in eleven hours seventeen minutes, or at an average velocity of 39.27 miles per hour. The fastest train on the New York Central runs from New York to Buffalo, 440 miles, making four stops, in ten hours forty-five minutes, or at the rate of 40 93 miles per hour. This is the South Shore Limited, which runs from New York to Albany, 143 miles, without stopping, at an average velocity of forty two miles per hour. The Boston & Albany runs a train from New York to Boston, 234 miles, at a mean velocity of thirty-nine miles an hour. The Saratoga Limited on the New York Central makes from forty to forty three miles an hour for a distance of 150 miles. On her Western trial trip in 1888 the Strong locomotive ran 116 miles in 116 minutes with a heavy train; but this is exceptional, and for a trial trip only, whereas the above figures are taken from printed time schedules.

Considering runs of less than 100 miles, we find that the Bound Brook express on the Central railroad of New Jersey runs from Bound Brook to Jersey City, thirty-one miles, making one stop, in thirty-seven minutes, or 49 8 miles per hour. The Pennsylvania railroad Congressional Limited runs from Jersey City to Philadelphia at the rate of 46.2 miles an hour, the distance being 89 miles.

These illustrations of the difference between velocity and endurance show us, then, that engines that excel in the one quality are frequently of comparatively little value as regards the other. This idea will be clearly brought out presently.

A tentative classification of the conditions of railroad traffic in this country would be as follows:

1. Light local—requiring locomotives with large drivers and quick, though comparatively light, steaming qualities.
2. Heavy express—requiring locomotives with smaller drivers and unlimited steaming capacity.

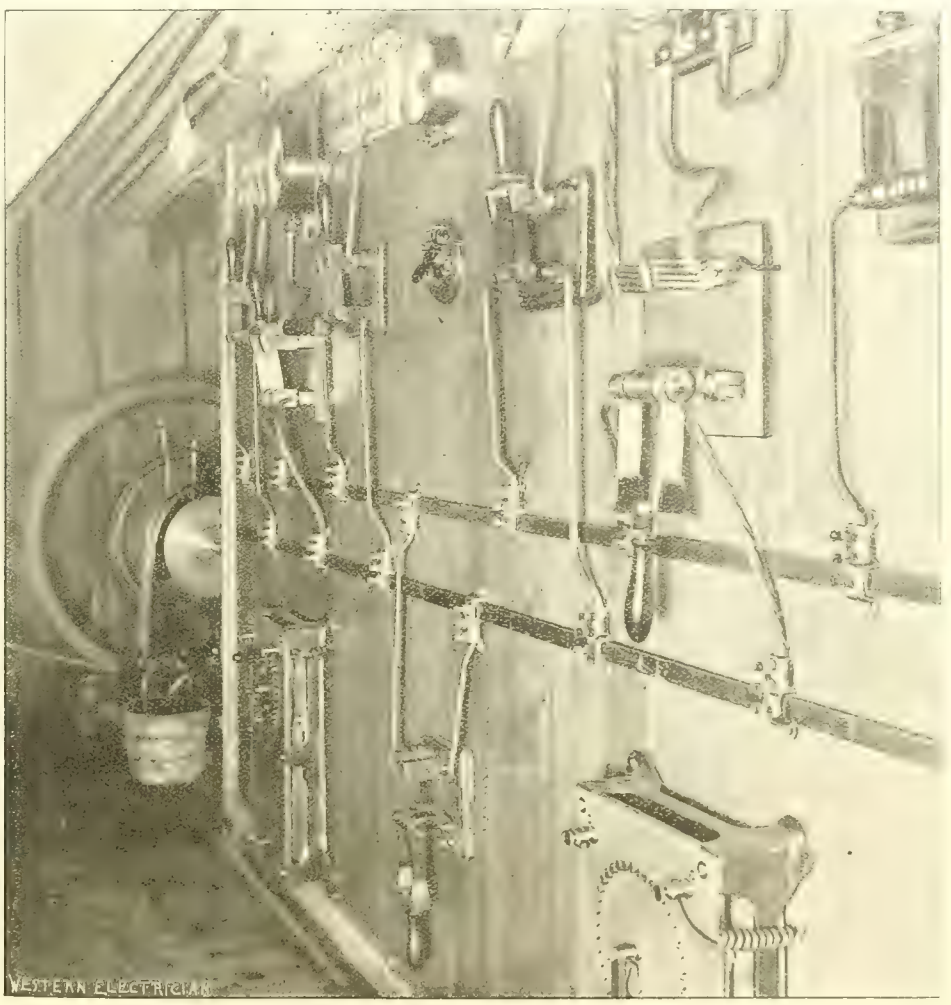

FIG. 2. ELECTRIC LIGHT PLANT ON THE VIRGINIA.

3. Mixed—such as excursion, suburban and freight trains, where the conditions are so varied as to preclude the designing of any one general type of locomotive, as will be seen upon comparing the enormous freight decapod with the far lighter four-wheel coupled engines, both of which are used in this class of service. On account of the varied character of this service, necessitating a special design in each instance, we can at once dismiss the third class from further consideration.

Class 1. Light local traffic so called, includes those trains that run back and forth between towns from ten to fifty miles apart, stopping at stations averaging from four to five miles apart. Such trains usually consist of four or five cars only, and sometimes as few as three. If we ride in the cab of a locomotive hauling one of these trains, and watch the engineer, we shall observe that he is constantly manipulating the mechanism in his charge. He starts up quickly, with his reversing lever down in the corner, thus admitting steam during nearly the full stroke; and within a minute he "hooks her up," or draws the lever up so as to cut off at an eighth or three-sixteenths, at the same time pulling out the throttle. This is the first phase. After running a couple of miles he closes the throttle, throws his lever down into the corner, and "lets her roll awhile."

and we may, if you please, consider this the second phase.

locomotive jars the pointer down a degree at least. Anxious

pound mark, we heave a sigh of relief at seeing the engineer close the throttle firmly. Round climbs the pointer as we roll along without steam, and soon we glide briskly up to the station with the escape valve roaring merrily.

What have we

must have large drivers—as large as is compatible with quick starting—in order to get

70 miles an hour

That she must make steam

large quantity. Endurance is of no importance in this class of engines; but the

essential.

Class 2. Now let me ask you to climb aboard another locomotive, standing at the head of a ten-car train of Pullmans. She has a hard task before her, as the run must be made from New York to Albany, 143 miles, without a stop. Starting out very slowly, with the greatest deliberation, the engineer begins to set her pace at twenty-five miles an hour. Little by little the lever is drawn up, little by little the long train responds to the pulling out of the throttle. Watch the gauge—160 when we started, it is now 155, after a half hour's run. At the end of the first hour the dial indicates 153 pounds of steam; and just then we slow down to scoop water. By the time the scoop is drawn up again we have 160 pounds pressure in the boiler. At last we run across the bridge into Albany with the gauge indicating 155.

This time we have learned: 1st. That the drivers must be considerably smaller than before in order that there may be enough leverage to start the train at all. 2d. That the boiler must be very much larger than in the former case, so as to easily deliver steam in enormous quantities for a period of three or more hours. This time velocity gives way to endurance in the matter of importance.

In response to the clamoring of the public for faster transportation, let us now endeavor to design a locomotive for the first class. To begin with, we must have large drivers in order to attain a velocity of 75 or 80 miles per hour. With a 5 feet 8 inch driver, 80 miles an hour means about 400 revolutions per minute, or with the ordinary two-foot stroke, a piston speed of

ute. We shall find in practice that

about the limit of piston speed in locomotives, as at that point the exhaust steam begins to choke so badly as to run the back pressure up alarmingly

mit the more steam we have to force

stroke.

But we can increase the exhaust orifice and thereby offer less resistance to the escaping steam

goes; but an increase in exhaust

in draft on our fire. Mr.

periments in that direction some three years ago, and found that a given

haust nozzles when serving in the

is working in the second and

with our experimenting and our figuring we learned that a

1. The editor of *Engineering* was evidently not well posted on American runs. At the time he wrote this article the Chicago Limited on the N. Y. Central was making a daily run from New York to Albany, 143 miles, without a stop.—H. S. W.

...well known, and a man back in the sixties had patented a valve which could be regulated at will by means of a lever in the cab. This invention never came into practical use, however.

Well, we can certainly increase the size of our drivers, thereby causing one revolution to mean nearly twice as much as it does now, and all this without increasing the piston speed—just as the English have accomplished in designing locomotives with 9-foot drivers. I think the records will show, however, that the English are cutting down the diameter of their locomotive drivers at the rate of an inch a year. We must remember that our trains are much heavier than those of the same class in England;

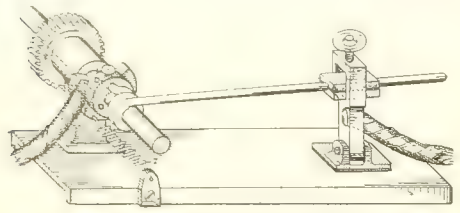

FIG. 1. ELECTRICAL METHOD OF SHAPING METAL BARS.

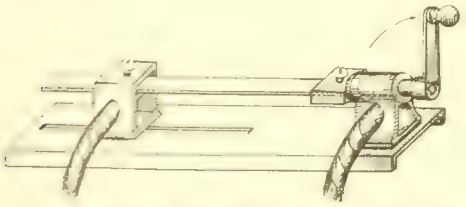
and if we designed our locomotives with such large drivers we should raise the center of gravity to an alarming degree, and be unable to start up at all. To overcome this last difficulty we might increase the power of our engines; we might add another inch or two to the diameter of our cylinders—and then run up against the old problem of how to get the increased volume of steam out again without killing our draft, or creating an abnormal back pressure.

So, we see, the light local locomotive of the present day owes its existence to the eternal fitness of things. The only apparent method left to us of increasing the velocity attainable with this locomotive lies in doing away with an exhaust steam blast, and substituting therefor a live steam blast. Suggest this, and you will become the legitimate prey of every division superintendent in the country. The most economical locomotive of to-day is a more wasteful machine than the old marine engine and boiler of forty years ago—and that is saying a great deal. Don't attempt any missionary work on the division superintendent; he'll get square with you by suggesting that it isn't worth while to make the exhaust nozzles of greater area than the exhaust part of your cylinder; and this leads to a consideration of valves, which I am not quite ready to enter upon.

Having considered possible improvements in the design of locomotives intended for the first class, we may now turn our attention to the second class, and endeavor to ascertain what modifications in our design will become necessary.

The drivers can be made somewhat smaller than before, as the velocity to be attained is not so great. Thus we can get the necessary leverage without sacrificing any other important quality. A heavy draft is, however, a necessity; and, leaving out of consideration the possibility of employing a steam blast (from questions of economy), we are obliged to wrestle with the old, old problem of how to eat our cake and keep it too—how to have small exhaust nozzles, and at the same time provide suitable egress for the dead steam.

The condition of unlimited steaming capacity demands a very large boiler. The problem growing out of this is,



...Von Waldegg and Fink obtain to a limited extent; but

...pared with the others, prevents the general introduction of any new designs.

The great drawback to the use of this standard link is due to the fact that there is only one valve, the action of which is such that the earlier the cut off the higher becomes the compression of dead steam behind the piston. To overcome this evil it has been proposed to employ a second valve, acting in conjunction with the main valve in such a way as to regulate cut off only (the main valve performing all the other functions), thus relieving the main valve in a measure of its overwork. This introduces complicated mechanism again, and for that reason is looked upon with disfavor. It is generally admitted, however, that when the ordinary steam pressure carried by our locomotives is increased to 190 or 200 pounds per square inch the double valve will become a necessity.

Nearly four years ago the then novel Strong locomotive created great interest in railway circles on account of its peculiar double legged boiler and its valve motion. Strong endeavored to apply to his locomotive what might be termed a modified Corliss principle. At the middle of the valve movement, the valve moved very slowly, but when admitting, cutting off or exhausting steam, it moved with a jump. A complicated gear, involving trip motions, accomplished this result. To-day the Strong locomotive is, I believe, but little mentioned, and then more as a historical machine than as one of the world's lasting inventions.

To sum up the argument briefly, we have found that the limit of velocity of the present locomotive is 80 miles an

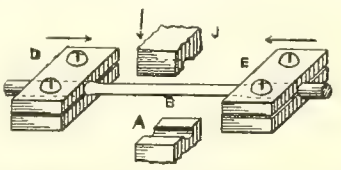


FIG. 5. ELECTRICAL METHOD OF SHAPING METAL BARS.

hour, and of its endurance 60 miles on hour. This proves conclusively: First, that even with improved roadbeds we can obtain an endurance of only 60 miles an hour; second, that our present method of laying tracks and ballasting them is such as to enable them to stand a train velocity of 80 miles an hour and over. Now, if our present roadbeds will stand a train velocity of at least 80 miles an hour, and if this velocity is the limit of our present locomotives, our only hope of more rapid steam transportation lies in increasing the endurance of our engines—and *not* in adopting a roadbed in accordance with Mr. Crosby's ideas, which had in view velocities of about 150 miles an hour. It is simply a question of designing a locomotive capable

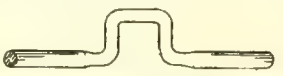

FIG. 6. ELECTRICAL METHOD OF SHAPING METAL BARS.

of greater power and higher velocity; and, whether this locomotive be intended for steam or for electricity, it must be a radical departure from any of our existing forms. We know that electricity can be employed as power in the coming locomotive; but whether it be *possible* to thus use steam remains to be seen.

THE BOOK TABLE.

DIE ELEKTRISCHE KRAFTÜBERTRAGUNG UND IHRE ANWENDUNG IN DER PRAXIS (Electric Power Transmission and Its Practical Application). By Edward Japing; edited by J. Zacharias; 3d Edition. 1891; 232 pages, 6x3½; 61 illustrations; A. Hartleben, Vienna.

The latest edition of this useful book contains many new and interesting data. It deals in plain language, avoiding the use of higher mathematics, with the problems of the generation, transmission, division and transformation of electric currents. One chapter is devoted to conductors and insulators and another relates to accumulators and their application for power transmission. We can recommend the study of this book to all those interested in electric power transmission and who are conversant with the German language. In another place is presented an abstract of the chapters treating of the "Rotary Current" (*Drehstrom*) and "Rotary Current Motors."

During the year ending July 31, 1891, according to the United States corporation bureau of Chicago, the total number of new incorporations reported was 14,854, with a total capitalization of $6,672,694,539. Of these, 1,139 were light, heat, power and transportation companies, with a capital of $[illegible]

The South Galveston & Gulf Shore Railroad company will build an electric railroad from Galveston, Tex., down the island to the suburb of South Galveston, a distance of about 20 miles. The city council has been petitioned for right of way on certain streets. Engineers are now surveying the route.

Electrical Method of Shaping Metal Bars.

The accompanying cuts illustrate several devices for bending and straightening metal bars and shaping metals by means of electricity. Heavy currents are, of course, employed. The current is passed through the section or bar to be operated upon until it reaches the required temperature, when it may be bent, straightened or shaped into any desired form by hammering or applying other suitable pressure. Fig. 1 shows a device for bending metal rods, such as steel bars suitable for heavy coiled car-springs. A shaft or mandrel, supported rigidly upon a pillar, similar to a lathe head, carries a dog or grip-piece adapted to grasp one end of the bar to be bent, the other end of which can be clamped in a guide or holding-clamp so as to allow

FIG. 3. ELECTRICAL METHOD OF SHAPING METAL BARS.

the bar to slip through it endwise. Current is conveyed through cables to the grip-piece and clamp between which the bars is held, thereby placing the bar in circuit. The current will be sufficient to heat the bar, while the other parts of the circuit should be made massive enough and of such good conducting material as not to be heated to any considerable extent. The pillar may be used to convey current, or a sliding contact held firmly with a spring will suffice to convey current to a revolving surface carried by the mandrel. A few moments after the current is turned on the bar will heat and soften, and when the mandrel is turned the bar will be easily turned into a spring or coil. The size of the bar that can be treated in this manner depends upon the capacity of the current to heat it and the massiveness of the apparatus.

In the device shown in Fig. 2 the clamps hold a flat bar of metal and they are also employed as conductors. The distance of the clamps is capable of variation by a slot in the bed-plate upon which a clamp can slide or be fastened by a bolt. Suitable guiding devices may be used to prevent the clamps from getting out of line. The clamp is attached to a shaft that may be rotated by the hand-wheel. When the current is passed through the apparatus, it heats the metal bar between the clamps. If the wheel is turned simultaneously with the passage of the current or shortly thereafter, the result of the operation, as shown in Fig. 3, will be a form suitable for a wood boring auger-stock.

In Fig. 4 a heavy shaft or bar is shown bent and gripped by the clamps, which are of considerable length, and are provided with V-shaped grooves to receive different sizes of bars. On account of the bend in the bar the movable clamp is not resting firmly on the bed. The passage of the current through the conductors brings the section of the bar containing the bend to a heated and flexible condition, allowing the movable clamp to be set down on the bed in line with the other clamp. If the current be cut off, the bar will cool while so held.

In Fig. 5 the section of bar between the clamps after being heated by the current is arranged to be formed with four bends by a depressed plunger or die *J*, which comes down on an anvil *A*, the clamps *D* and *E* approaching each other at the same time. The result is a crank-shaft, as indicated at Fig. 6. If the clamps *D* and *E* are actuated so as to permit the ends of the bar *B* to approach

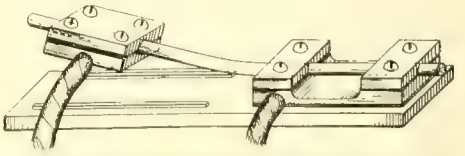

FIG. 4. ELECTRICAL METHOD OF SHAPING METAL BARS.

in an axial line, the parts *D* and *E* will be true with each other. The system was devised by Elihu Thomson.

Edison Removal in Chicago.

The removal of the office of the central district, Edison General Electric company, took place on August 15th. Leaving the Rialto building, the company has now taken possession of the fine five-story building at 173 and 175 Adams street, Chicago. This will afford ample accommodation for the extensive establishment of the Edison company. The offices are situated on the second and third floors. The main floor is being fitted up as an exhibition room, where will be shown samples of the numerous appliances handled by the company. The arrangements are not all finished as yet, but when completed the establishment will lack nothing conducive to the comfort and convenience of employes and patrons.

Diminutive Electric Light Plant.

E. A. Maxwell thinks that the little plant illustrated herewith is the smallest of its kind in the country. He installed it in his workshop in Salina, Kan., on March 3rd, and regards his work with considerable pride. The room is 30x14 feet, and is lighted from this lilliputian plant by seven incandescent lamps. The little dynamo is driven by a two horse power engine, coupled directly to the generator, as shown in the illustration. The plant has been in operation every day since its first installation, and has worked satisfactorily.

The Montreal Convention.

The committees having in charge the arrangements for the Montreal Convention of the National Electric Light association have about completed their labors, and the outlook for the meeting is unusually promising. A large number of electrical concerns have applied for space for exhibits, and the display of electrical devices and supplies will be highly interesting and creditable to the association.

The committee on transportation announces for the benefit of eastern delegates and visitors that arrangements have been made for a special train leaving the West Shore station at Weehawken, N. J., at 10:05 Sunday morning, September 6th, and arriving at Montreal at 10:15 P. M.

For the convenience of New York delegates a representative of the railroad company will be at the Electric club, 17 East Twenty-second street, New York city, on Saturday, September 5th, from 3 to 6 P. M., to furnish tickets and information. Boats connecting with the train will be run as follows: West Shore ferry house, foot Jay street, 9:45 A. M.; West Forty-second street ferry house, foot West Forty-second street, 10:00 A. M.

The following list of exhibitors at the convention has been prepared by the secretary: Eureka Tempered Copper company, North East, Pa.; Chas. A. Schieren & Co., New York; Standard Underground Cable company, Pittsburg, Pa.; W. J. Johnston company, limited, New York; Standard Electrical Time company, New Haven, Conn.; Standard Paint company, New York; Fort Wayne Electric company, Fort Wayne, Ind.; Electrical Engineering & Supply company, Syracuse, N. Y.; Eugene F. Phillips Electrical Works, limited, Montreal, Canada; Felten & Guilleaume, Cologne, Germany; International Okonite company, New York; Weston Electrical Instrument company, Newark, N. J.; The Johns-Pratt company, Hartford, Conn.; the Ball Electric Light company, Toronto, Canada; the *Electrical Engineer*, New York; Interior Conduit & Insulation company, New York; Robert Mitchell & Co., Montreal, Canada; Thomson-Houston International Electric company, Boston, Mass.; Toronto Construction & Electrical Supply company, Toronto, Canada; H. Ward Leonard & Co., New York; Dominion Wire Manufacturing company, Montreal, Canada; T. W. Ness, Montreal, Canada; Edison General Electric company, New York; Norwich Insulated Wire company, New York; Excelsior Electric company, Boston, Mass.; Canadian Electrical Construction, Manufacturing & Supply company, Montreal, Canada; Russell Electric company, Boston, Mass.; *Electric Power*, New York; McGill University, Montreal, Canada; La Boiteaux Electric Motor & Fan company, Cincinnati, O.; WESTERN ELECTRICIAN, Chicago.

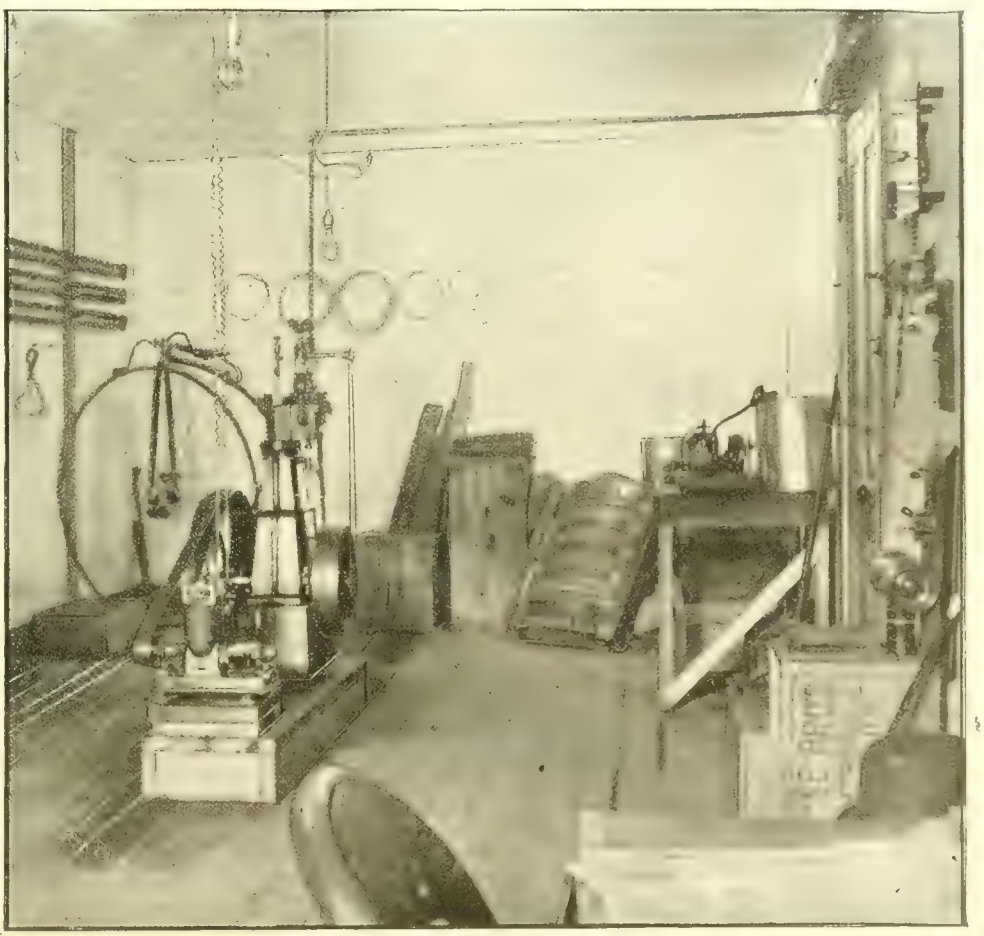
American International Telephone Cable.

The completion of the St. Claire tunnel had a peculiar interest to the telephone people as it marked the completion of the first American International telephone cable. Inaugural opening ceremonies of an international character will be held September 19th. The tunnel passes under the St. Claire river between Port Huron, Mich., and Sarnia, Canada, on the line of the Chicago & Grand Trunk and Grand Trunk railways. It is finished from the American to the Canadian portals, and the work on the approaches is rapidly nearing completion. Ground was broken on this great work on new year's day of 1890. It is estimated that $2,500,000 will have been expended on the tunnel before a train passes under the water. The tunnel itself, from portal to portal, is 6,025 feet long. The American approach is 1,500 feet long from the starting point on the surface level to the mouth, and the Canadian approach is 2,000 feet long.

The telephone cables are already placed in position, and the line will probably be formally opened about the same time as the railroad business.

Amateur Electricians.

On the evening of Aug. 20th a meeting for the formation of a national association of amateur electricians was held at the Grand Pacific Hotel, Chicago. O. E. Cozzens presided, and a constitution and set of by-laws were adopted. Nearly sixty members were enrolled, with every indication that this number would shortly be increased to several hundred. Applications for membership were received from



DIMINUTIVE ELECTRIC LIGHT PLANT.

Atlanta, Ga., and Toronto, Ont. The society intends to encourage the study of electricity among young men who propose making it a profession, and those who are merely interested in such studies. Arrangements have been partially made for an exhibition at the World's Fair. The name adopted is the American Society of Amateur Electricians.

The Alternating System and Long Distance Transmission.

To the Editor of the WESTERN ELECTRICIAN:

In one of your esteemed contemporaries I find a review of the "Electric Transmission Hand Book," in which the following sentence occurs:

"Mr. Badt apparently is no believer in alternating current transmission of power, but if he had followed the progress of the times a little more sharply he would have been aware that the alternating system for long distance transmission is looming up in a way that leads one to the conviction that it will find a very large amount of use in the class of work before mentioned."

I cannot see what put this erroneous idea in the reviewer's head, unless it is my statement on page 47 of the handbook: "As long as alternating motors cannot be made self-starting and automatic in regulation, of high commercial efficiency, and be built in as large units as continuous cur-

[illegible] the multiphase alternate current transmission between [illegible] that this experiment will differ vastly from Brown's preliminary experiments at Oerlikon. The latter experiments, which I mentioned in the book, still remain "experiments."

[illegible] friend, C. [illegible] "Please find inclosed photograph of a 300 horse power three phase alternator. This machine will enable me to carry out my previous experiments, for the first time, from Lauffen to Frankfort."

Telegraphers' Conventions at Washington, D. C.

The conventions of the Old Time Telegraphers' and the Military Telegraphers' [illegible] last week proved very satisfactory. Steps were taken [illegible] different [illegible] association complete historical data with a view to the publication by the association of the history of the early development of the telegraph in America.

The election of officers for the ensuing year resulted as follows: President, Edward Rosewater, Omaha; vice president, George M. Dugan, Jackson, Tenn.; secretary and treasurer, William J. Dealey, New York.

The Military Telegraphers' association re-elected the officers of last year. The principal topic discussed was the subject of securing recognition from Congress for the surviving members of the corps. The next meeting of the convention will be held in Omaha, Neb., on the third Wednesday in August, 1892, in connection with the meeting of the Old Timers' association at that place.

The Washington convention gave the members and guests an opportunity of visiting many interesting spots. The grand reception was one of the most attractive features of the meeting. Messages were received in the hall from all quarters of the country, many notable men sending greetings and expressions of good will. One of the most interesting dispatches was the following:

"To the Old Timers and Military Telegraph corps: The operators in the land of the Montezu[illegible] [illegible] City of Mexico."

During the evening speeches were made by many government officials. Assistant Secretary of War Grant's remarks were eulogistic of the work of the "boys," as he called them, during the war, and the secretary called forth loud applause when he said there was but little difference between the telegraph line, the line of duty, and the line of battle. During the war it was generally a race between the operator and the army, and the operator was generally ahead.

"I think," said Secretary Grant, "these boys should be recognized as soldiers, and recognized by this government." As he concluded the secretary paid a tribute to the work of the profession generally and the usefulness of the "mysterious click, click, as mysterious as old Nick."

Chicago Edison Company.

At a meeting of the stockholders of the Edison company held last week it was decided to increase the capital stock of the company from $[illegible] to $[illegible]. The extension is to go into effect probably within the next six months. The additional stock will undoubtedly all be taken by the present stockholders. The proceeds will be used to defray the cost of recent improvements.

The Montgomery, Ala. [illegible] company has applied to the city council for authority to change its street railway to the electric system. The estimated cost of the improvement is $80,000.

[illegible] system of electric railways, lights and [illegible] proposed for Staten Island by Erastus [illegible]. It is [illegible] that with the proposed improve[illegible] would be a boom to the island that would [illegible] of the [illegible] Mr. Wood has [illegible] and [illegible] to [illegible] engineers to [illegible].

[illegible] in London [illegible] system in [illegible] Manchester [illegible] are [illegible] ure of this system, but these statements invariably emanated from unreliable sources and in every instance it has been shown that they were circulated in the interest of the elevated roads. Authentic reports of the business transacted by the London company show a handsome profit and increasing patronage. Of course there have been drawbacks—they were to be expected—and many alterations and improvements may yet be required but the advocates of the "L" roads can not boast of a perfect system. In fact, so little advancement has been made by the "L" management that it is is hardly noticeable. The London underground railway to-day is far superior in every respect to the New York "L" system.

The Rapid Transit commission of New York should lose no time in pushing forward a comprehensive scheme for underground electric railways.

THE convention at Montreal from a social standpoint will doubtless surpass all former meetings. The preparations have been made on an elaborate scale and the attendance will no doubt be much larger than is customary at mid-summer conventions. There is much to interest visitors in Montreal, and the presence of a representative gathering of electrical men will stimulate interest in the advancement of electrical industries in Canada. The preparations for the literary part of the convention are on a scale commensurate with other features of the meeting.

WILL the new three phase alternating current prove of sufficient commercial utility to warrant its general introduction in power transmission? This is a question that is now exciting wide attention from the electricians of both Europe and the United States. The rotary current, or *drehstrom*, originated in Germany, and its first application in long distance transmission will be between Lauffen and Frankfort. Until the result of this experiment is known the query forming the first sentence of this paragraph will remain unanswered. The test, therefore, assumes a double importance, as the trial of a new system and as the most extensive feat of electric transmission yet attempted. This and Mr. Tesla's experiments in New York are undoubtedly the greatest features of electrical advancement of the year. The outcome of the former is awaited with keen interest. Meanwhile the American reader can obtain a good general idea of the new current by reading the translated abstract from Herr Japing's book, presented on another page of this issue. A motor whose armature is practically without winding is a sufficient novelty to challenge the attention of every electrical engineer.

THE electrical interests will not be disposed to indulge in any unseemly exultation over the decision of the executive committee of the directors of the World's Columbian Exposition to the effect that the chief of construction must "first obtain in writing the concurrence of the committee on electricity, on all matters pertaining to electricity, electrical and pneumatical appliances, and all plants connected therewith, before submitting the same to the grounds and building committee for action." Nevertheless, the decision is exactly in line with the principle for which the committee on electricity and the electrical department have been contending, and it is gratifying that the position taken by the electrical fraternity has been sustained. By the terms of this resolution it will be impossible, it would seem, for the construction department to totally ignore the electrical representatives in matters appertaining to electrical installations, as was done when Chief Burnham advertised for bids for the temporary electrical plant. This is a great point gained. On this basis of fair play a harmonious agreement should now be speedily reached. The WESTERN ELECTRICIAN earnestly hopes that such an understanding will be arrived at, and that hereafter the departments will work together in perfect accord.

THE discussion of electric mining machinery is just now of more than ordinary interest. In another column is presented a synopsis of an interesting discussion of this topic before the Institute of Civil Engineers of England, where a comparison of compressed air and electricity was favorable to the latter.

An interesting point discussed was the alleged danger from explosions in coal mining. In the case of a motor in constant service for many hours, it was necessary to guard against the accumulation of explosive atmosphere around the brushes it was claimed. For this purpose it was suggested to inclose either the whole armature or the commutator only in a practically air-tight casing. The method had been successfully applied to a motor of 50-horse power. The temperature had been kept down to 50 deg. F. [illegible] above that of the atmosphere by allowing a sufficiently large cooling surface, namely 2.3 square inches per watt. To meet the objection that if the fire-damp should leak into these covers the resulting explosion might be as disastrous as if they did not exist, it was pointed out that 'whenever the proportion of marsh gas to air exceeded 3 to 4 per cent. combustion would take place quietly, and the resulting carbonic acid would tend to prevent explosion in the case of further leakage." Precautions were also suggested for the switches. Many devices were minutely described and their advantages discussed. The conclusions reached were highly satisfactory from an electrical standpoint.

AN advocate of electric heating in dealing with the question of expense calls to mind the fact that in other departments of domestic and commercial life refinements and improvements have only been secured at increased cost. In illustrating this point he says: "The electric light is more expensive than gas, but also is gas more expensive than oil, and oil than the tallow candle, yet, even considering the item of expense, who would not prefer the incandescent lamp to the candle, oil or gas? Thus the cheap wood fire gives place to the more expensive coal fire, and the coal fire to the more expensive natural gas fire, and it, in turn, to steam."

There are many advantages attending the adoption of an electrical system of heating, and many disagreeable accidents are avoided. Even the item of cost may be brought reasonably near that of older systems. It is proposed for example to establish one power station for 20,000 inhabitants to which fuel may be brought by railroad, and where a half dozen men can perform the necessary labor. It is shown that the expense of installing this plant will not equal the "initial cost of the separate furnaces necessary to the population; nor will the wages of the station men amount to that of coal heavers, draymen and separate assistants in the homes. The wear and tear of the apparatus cannot equal that of small heat systems which also call for wear and tear upon trucks, horses, public and private property." Another advantage of electric heating is the absence of dirt and noise. The power stations from which current could be supplied for heating purposes would be located some distance from the residence district of the city. The fuel which otherwise would have been wheeled through the streets of the city, dumped upon lawns and sidewalks, thrown into cellars, creating dust, dirt and noise, and later requiring the labor of hundreds of people to feed it to furnaces, and to carry it to stoves and grate, and which would require the attention of the family to accomplish satisfactory and economical combustion would be in the furnace of this power station, consumed under the direction of two or three men skilled in such labor.

VALUABLE statistics on street lighting in the principal cities of the country are presented in another column of this issue. The data were prepared by the census department and published in an official bulletin. It appears that of the twenty-two cities named, each of 100,000 inhabitants or more, St. Louis leads in the actual number of electric lights employed in street lighting Rochester follows with Denver third, Brooklyn fourth and New York fifth. Many of the smaller western cities make a far more creditable showing than the older and larger cities of the East. New York is far behind in the race and Chicago has only recently entered the lists. It should be borne in mind, however, that the figures presented in this statement do not fairly represent the development of electric lighting in the cities named. In New York for instance, there has been a bitter fight between the local lighting companies and the city officials. The war on overhead construction of course greatly injured the business of electric lighting companies in the metropolis and this is shown by the small number of street lights. But it should not be forgotten that in many of the large buildings in New York and Chicago there are isolated plants whose capacity is greater than that of the combined output of the plants of many pretensious towns.

Cincinnati is the only city of importance in the country that has no electric street lights. It should be, and probably is, heartily ashamed of itself. The table of lights given on another page would be more valuable if it showed the number of arc and incandescent lamps on the streets of each city, with the average cost of each. The figures showing the relative cost of electric lighting would then possess much greater importance. They would explain why in Rochester, for instance, where a large number of 32-candle power incandescents are used on outlying streets, the average rate is so much lower than in most other cities. In San Francisco the high rate is probably caused by the greatly increased initial cost of plant and the high rate of wages prevailing, while the low prices ruling in New England towns are undoubtedly due to lower prices for labor and machinery, and, in many cases, to the employment of water power. On the whole, the bulletin is one of the most useful so far issued by Superintendent Porter.

New Feeding Mechanism for Arc Lamps

An improved automatic feeding device, by which the position of the carbons in an arc lamp is not affected by gravitation, enables C. & E. Fein of Stuttgart, Germany, to make a novel and attractive exhibit at the Frankfort exhibition. On a large iron drum rotating on a shaft and resting on an iron framework are placed six large arc lamps extending radially from the periphery. The drum is

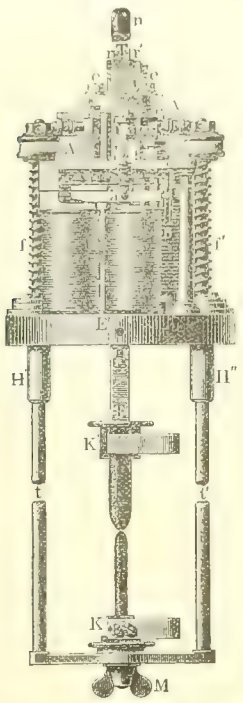

FIG. 1. NEW FEEDING MECHANISM FOR ARC LAMPS.

kept rotating by a small electric motor at the base of the frame, and the lamps continue to burn, as the drum rotates, either vertically, horizontally or in an inclined position. Neither is the steadiness of the light in anyway disturbed.

The construction of this lamp is shown in Fig. 1 The upper carbon holder *K* is fastened to a square brass tube *T*, which is guided by three friction rollers. These are placed in a movable frame, which, when operated, causes the upper carbon to approach the lower. The action of the friction rollers is governed by a set of levers and gear-wheel *B*, and operated by a shunt magnet E^1, and the approach of the carbon is proportional to the degree of attraction of the armature *A* on the magnet. The connection to establish the arc is made through the main current magnet *E*, its anchor *A* and the lower carbon K^1. The mechanism of this lamp is very compact, and it is intended that its regulation shall be perfect. The fact that it will work successfully in any position gives the lamp a very wide field, and makes it especially well adapted for marine installations, for portable lamps and reflectors. It is asserted that the lamp is peculiarly adapted for search lights.

The mechanical construction of the lamp when used in connection with a reflector, as a headlight, for instance, is somewhat different, as shown in Fig. 2, although the prin-

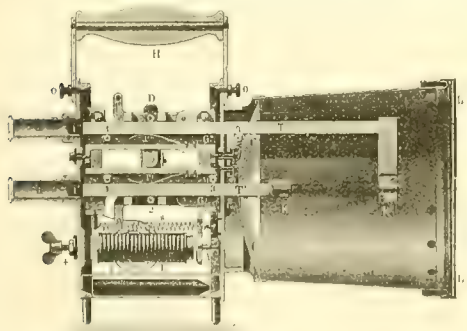

FIG. 2. NEW FEEDING MECHANISM FOR ARC LAMPS.

ciple is the same. The efficiency claimed for this lamp is remarkably high. Three different sizes—5,000 candle power, 1,000 candle power and 200 candle power—are made. The last and smallest size is said to require only one-fifth of a horse power, with two amperes current. If this is correct, there can be little doubt that a small lamp like this is the most economical form for utilizing electrical energy as light.

Fig 3 gives a perspective view of the lamp arranged with a reflector. The illustrations are reproduced from *Electrical Engineer*.

Telephone Stock and the Bell Patents.

The impression that the telephone field will be open to all comers within a short time has taken possession of many capitalists and speculators, and the effect of this belief is plainly seen in the direction of their operations. The *Daily Financial News* recently presented the following "advice about Bell telephone" stock which will be read with interest by the electrical fraternity generally:

There is one prominent stock in the market that it would be well for holders to get out of, not because there is anything wrong either with its present earning capacity or with its management. It is simply due to the fact that the ravages of time have cut down the period which its principal patents have to run, and at the end of this time, now only about two years, the many advantages it now enjoys from the protection of its patents will cease.

The stock in question is the American Bell telephone. It has already fallen 50 points from the price at which we began to recommend its sale, and we believe it is good for a further decline of 70 points within the next year.

The strength of Bell telephone has been its patents.

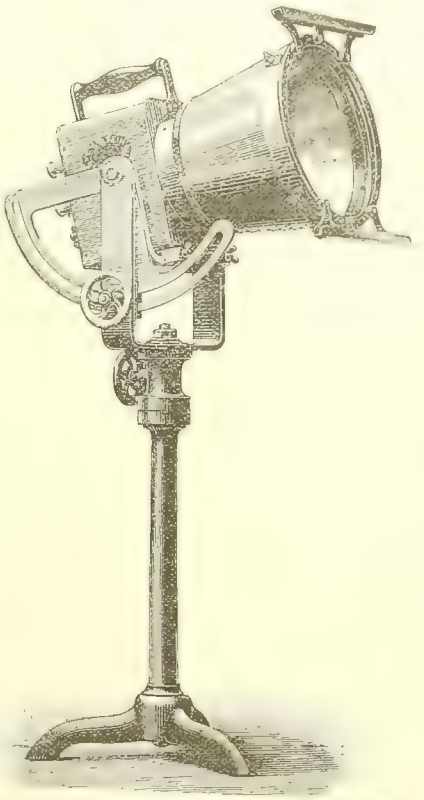

FIG. 3 NEW FEEDING MECHANISM FOR ARC LAMPS.

The most valuable of these expire soon, and some of the English patents have not very long to run. Hence the question arises, How will that leave the American patents? Is the Bell telephone in a position outside of its patents to maintain its present earning capacity? We don't think so.

One thing in this connection is worthy of note. The opinion has prevailed for some time that the patent of the Blake transmitter ran out in July last. This is not so. It will not have passed the existence of her gracious majesty's patent laws for at least another year, or perhaps until early in 1893.

At all events, the Bell telephone will soon have to encounter the most active and aggressive competition. Hence, to the wise who want to unload their stock, these words of warning ought to be both timely and sufficient.

The Grassot Electric Meter.

The accompanying illustrations represent a new electric meter devised by Emile Grassot It belongs to the group of quantity-meters or ampere-hour meters, and, like the Edison meter, is based upon the chemical action of the current. Fig 1 is a front view, while Fig 2 is a side elevation of the instrument. It is composed of a stone or glass jar *A* containing a solution of acetate of silver in the proportion of 1 to 10, and has an anode *b*, and a cathode *a*, each of which is made of a fine silver wire equal in size to number 24 B. and S. gauge. The anode *b* is placed inside a glass tube *B*. It is pointed at its lower end and has an opening large enough to admit the passage of the silver wire. This wire rests against a point *c* of a glass hook *C* fastened to the cover of the jar. The part of the anode which is exposed to the action of the solution is about ¼ of an inch long. The glass tube *B* is made in two pieces, of which the lower part is fastened in the center of the cover *D*, which also serves as a support for a registering movement or counter insulated from the cover.

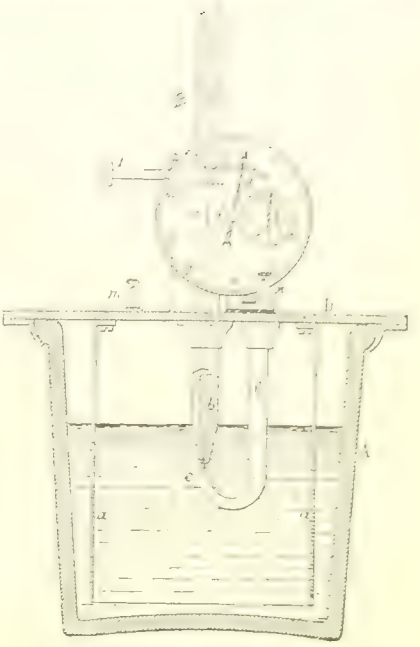

FIG. 1. THE GRASSOT ELECTRIC METER.

of this meter will now be easily understood. Under the action of the current the anode *b* dissolves, and the metal is deposited on the cathode *a*. As the dissolution of the anode takes place gradually at the point, the silver wire is forced down by its weight, at the same time rotating the drum *d*, thereby registering the amount of wire consumed, or by transformation the number of ampere-hours consumed. The placing of the meter in the circuit is done in the same way as an incandescent lamp, excepting that sufficient resistance must be inserted to reduce the current to about 1-1000 part of the total current.

This meter is in operation at the station of the Halles in Paris, and is spoken of very favorably in regard to accuracy and simplicity of manipulation. The cuts are reproduced from *L'Industrie*.

English Electrical Exhibition.

The West of England and South Wales electrical engineering exhibition was opened at Taunton on Aug. 1st by Field-Marshal Sir Lintorn Simmons, late governor of Malta. Prior to the opening ceremony Sir Lintorn was entertained at luncheon at Clarke's Hotel, at which were present a large number of influential residents, including the mayors and other officials of many of the neighboring

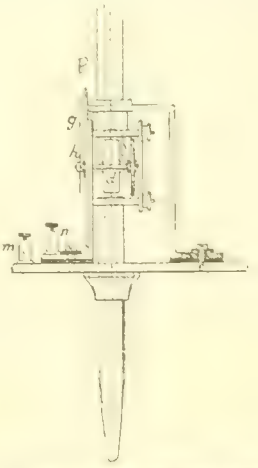

FIG. 2. THE GRASSOT ELECTRIC METER.

towns and districts. Sir Lintorn, in replying to the toast of his health, gave some interesting details of the most recent applications of electricity in connection with naval operations. H. G. Massingham gave a few details of the history of electric lighting in Taunton which was inaugurated by him in 1885. At that time he purchased his own cost an experimental installation to afford the

...dging of the merits of the Thomson-Houston system of arc lighting.
